Either way, do we know the impedance? That is an "easy build" and I want to try some single-band, no-tuner HF antennas. I cut one for 350 MHz receive-only some years back (for the Blue Angels' radios at an air show) and it worked fine.

One more thing: Assuming a nominal 50 ohm match can usually be made, is there any drawback to tuning the thing by making the braid a little longer than calculated, moving the end of the braid up and down to find the best match and then securing the end? I mean, if you don't mind a somewhat lumpy-looking sleeve. (I'm a bit lumpy-looking, myself.) The decoupling capacitance would be reduced by both the decrease in length and the increase in spacing, but the changed value would be, in effect, part of the tuning.

"Sal"

It's a dipole, so it should look like 50-75 ohms to the feedline. I'm not
sure I follow your line of thinking in regard to moving the shield up/down.

That's complete BS. In 1979 we had 1/3 the number
of licensees that we have today, yet the '79 WARC
gave us three new HF bands. We do not need large
numbers to keep what we currently have.

Please abide by the followup-to line above.

4. Acceptable Lightning Ground?

Newsgroup: rec.radio.amateur.antenna

Source record: 47268

I would like to propose a grounding arrangement for my [hypothetical] antenna and get some feedback on it. I have access to the solid-copper cold-water pipe that enters my home through the basement wall close to the basement floor. This pipe is used [in addition to cold water] for the service entrance [circuit breaker box] ground. I was thinking of putting an antenna outside on a pole and running the coax into the basement. Then I would strip back several inches of the outer jacket of the coax [axposing the braided shield] and connect the coax braid to the cold water pipe using several hose clamps. This should ground the coax directly to the service ground - the single point ground for the house. I would add an arrester near the ground point. I would then run the coax upstairs [about 10 feet] to the radio, where it would [via the PL-259] connect to the transceiver chassis. The radio chassis will be electrically bonded to peripheral equipment chassis'.

It seems that in the unlikely event [low altitude, semi-urban area] that the antenna were struck by lightning, the energy [albeit significant] would have no reason to propagate up to my station. Even though it may elevate my house ground by thousands of volts [with respect to some other ground point], the station should ride up with it - and little current should flow in the coax at the station.

Am I whistling Dixie?

Thanks,

-JJ

nope, not the way to do it right.

except the single point shouldn't be 'inside' the house.

the radio chassis should be connected to the same single point ground, and
not via just the coax shield.

Hi OM,

The sleeve dipole makes for a pretty tall HF radiator and puts one end
quite close to ground where a ground plane design, if you matched the
heights of the feed points, would probably show less loss.

As for impedance, it would be close to a conventional dipole - 70 to
75 Ohms. However, the proximity of earth (for HF) would alter that.
Further, the jacket material that covers the outer braid is notorious
for being rather lossy in its own right. When you draw the braid back
over it, it creates a lossy transmission line with that material
between the drawn back braid, and the jacketed braid it is covering.
This does not normally concern most who build this style of antenna as
it is one of those "precious" details that is argued endlessly while
others put it to good use.

It'll work just fine.

This is the first I've heard of "decoupling capacitance." The lower
arm of the vertical dipole is just that, the lower arm. It's
proximity to the feed line will certainly impact the state of tune,
but there is no claim to decoupling built into this design. You will
have to provide for the usual considerations in that regard (but most
neglect that too to no particular pain).

Good one Dave. When you start "studying" for your general you will see how dumbed down and simple it is and you might marvel at why the QPC would have ever even bothered to commit such a "test" to publication. It may also occur to you that, as the the Geico commercial says, it is so easy a caveman could do it. Actually I would move back perhaps 25 million years earlier in the evolutionary cycle and say it is so easy, even a monkey could do it.

And monkeys it will be.

The new Monkey General class :-)

Hi OM,

You have the classic service ground connection.

>I was thinking of
>putting an antenna outside on a pole and running the coax into the
>basement. Then I would strip back several inches of the outer jacket
>of the coax [axposing the braided shield] and connect the coax braid to
>the cold water pipe using several hose clamps.

This qualifies, in most respects, to code for grounding a continuous
wire and employing a method prescribed by code, clamping. However, it
would seem that clamping might deform the coax. You should
investigate your local code for alternatives as well as for
compliance.

>This should ground the
>coax directly to the service ground - the single point ground for the
>house. I would add an arrester near the ground point.

Then you are breaking the run instead of just simply stripping the
jacket. Check code.

>I would then run
>the coax upstairs [about 10 feet] to the radio, where it would [via the
>PL-259] connect to the transceiver chassis. The radio chassis will be
>electrically bonded to peripheral equipment chassis'.

This is also classically known as a suicide connection. If you were
holding the PL-259 shell in one hand, and touched any, poorly
maintained metal chassis of the transceiver while plugging it in (or
removing it); then you might just be the fuse in a circuit about to
blow. I've seen my buddy draw sparks with just such an arrangement
before I convinced him to run a real, separate ground.

13. Interesting 144 foot Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-01 18:49:30 UTC
From: Cecil Moore <mycall@hotmail.com>
Message-ID: <_Icmh.31175$Gr2.1959@newssvr21.news.prodigy.net>
Source record: 47278

A ham over on eHam.net wanted to know if a 40m EDZ would work on 80m. Of course it will if fed correctly since it is about 166 feet long. The question is: Is there a fixed length of ladder-line that will work both on 40m and 80m? I fired up EZNEC and started cut and trying. I found that a 144 foot 40m "EDZ" would yield some interesting results. I went out and extended my 130 foot dipole to 144 feet and was impressed.

I found that a 144 foot center-fed dipole fed with ~88 feet of 450 ohm ladder-line was resonant on 7.150 MHz and my IC-756PRO would tune it over the entire 40m band. 40m is my favorite band.

In addition, the IC-756PRO tuner will tune the same antenna system over a 3.7-3.9 MHz range on 80m.

In addition, the IC-756PRO tuner will tune the same antenna system on 30m and 17m.

I've already got a rotatable dipole for 20m-10m and this antenna tunes on 80m, 40m, and 30m.

You haven't described here the antenna and its support structure, and
they are relevant.

One of the strategies for hardening a site against lightning is to divert
as much of the strike current to ground rather than having it flow in the
conductors within the facility. The value / necessity of this measure
will depend on the antenna, its support structure, nearby structures that
might protect your antenna to some extent, and the risk of lighting in
your locality.

Lightning conductors need to be substantial enough to withstand the
strike scenario without physical failure (eg melting). A common scenario
is 20kA for 0.1s, but it does depend on the situation. Is your coax braid
and your termination / bonding method sufficient to survive strike
current?

Equipotential bonding of the lightning protection ground and the AC
service ground systems is important. Low resistance and more importantly
low inductance conductors that will withstand the current are required.

Depending on your coax shield as a bonding conductor from your equipment
to the ground point as you describe sounds unwise for several reasons,
but most notably because it uses coax connectors (and probably PL259s at
that) for the connection, they are not reliable enough, and they would
not be a permanent connection).

If your equipment runs on low voltage DC, do not assume that the power
supply provides a connection between the AC ground and the -ve DC lead,

some powersupplies have floating output. In any event, bonding of the external metal of all equipment in your station to a single point ground is advisable to reduce the risk of substantial potential differences between equipments, and the risk that poses to life in the event of lightning or even an electrical fault.

If addressing these issues seems extreme, it is probably a good indicator that many ham station earth systems are quite inadequate, offset by the low probability of an adverse event and not usually talked about when poor implementation exacerbated the situation.

Like one of the other respondents, I recommend the Polyphaser site, it is a usefull source that canvasses many of the issues.

Additionally, your wiring codes or standards may provide guidance or set requirements, they do here.

Having done all that, and with better knowledge, review the risk, cost and measures. You may not want to resource a lightning hardened solution for 24x7 connection of the stations to antennas.

Owen

One of the other posters in this thread gave me the solution to my quest, and it was cheap, easy, small, and less than 1.3 SWR. It was a simple dipole, made of a wooden block and welding rod. I took a piece of 3/4 inch wood dowel, cut it to about 4 inches in length, drilled one hole in each end (lengthwise). I left about 1/2 inch of wood between the holes I drilled, so the welding rods would not touch. I inserted a 19 inch piece of welding rod in each end. The overall length is about 38 and 1/2 inches. Then, in the center of the dowel, I drilled two intersecting holes so that I could put screws into the wood which would press against each piece of welding rod. This kept the welding rods in place, and it also gave me a place to attach the center wire and braid from an RG-58U Coax cable. I soldered two small alligator clips, on the coax, so that I could just clip the coax to the antenna. To take it apart, or put it together, all I need is a phillips screwdriver.

I'd like to thank everyone for their help, in pointing me in the right direction!

I made one of these sleeve antennas for 10M with the folded back shield,
put a KW on it and it arced through the black vinyl.
Not exactly what I would call a "precious detail". Many years ago Shakespear
antennas were made this way and they changed there design because of the
same problem. Now they replace the folded back sheild with 4 or 5 wires
imbeded in the fiberglass shell putting a good bit of air dielectric between
the folded back part of the dipole and the sheild.

Hopefully you are not really using the water pipe for a ground for your electrical service. Hopefully your plumbing is just bonded to the electrical ground. Dont even think about using this for lightning protection. Nothing like having lightning run in on your plumbing while taking a bath or have it run in on yor ground and eat about $7K worth of test equipment(my bad).

Jimmie

Only one amateur on RRAP has ever said that studying wasn't required.
He was an Advanced and his name is/was Bruce. Said he took the Extra
exam on a whim, a bet, and took $250 from a "No Code CBer." Passed the
exam without any preparation, and didn't miss a single question.

However, Bruce was the closest thing to a Monkey that you'd find on
RRAP.

It's a standing wave antenna. The voltage at the end
of the shield is approximately 20 times the voltage
at the feedpoint. For a KW, that's more than 5 kV,
too much for ordinary coax.

Well, I finally took the time to work on the "TV Antenna Feed Line" J-Pole someone suggested. I got it down to less than 1.6 SWR, on 2 meter, and less than 1.2 on 70 cm, by trimming it down 1/8 inch at a time. So now I have a VERY portable dual band antenna, I can just roll up and stick in a small "go bag". I tried it on my Yaesu VX-6R and was able to hit several local repeaters, some, of them even on low power.

Thanks again to all that helped.

A little trick I learned in AZ - It will work better
on 440 if you slant it toward the repeater.

John, re the lighting protection issue with the tuner.

I don't need or want to operate when there is a high risk of lightning, so I disconnect the tuner. The last picture in this article shows how the tuner is mounted and the simplicity of an effective isolating switch. In the event of lightning strike, the inverted L wire will probably side flash to the support mast where it is much closer. One could of course build a sturdy arrestor near the tuner if you don't have such an alternative.

http://www.vk1od.net/InvertedL/InvertedL.htm

Pleased it is all working well for you.

Owen

Greetings,

I'm thinking I want to move off of the repeater scene and start getting involved in 2-meter SSB. Around here, horizontal is the only way to go with that.

I'd like to put an omni-directional 2-meter horizontally-polarized antenna on top of the 10ft mast on my roof that is currently hosting my GP3 (this will replace the GP3). Mainly, I don't want to mess with a directional beam and a rotor.

Any recommendations as to a store-bought unit that might be well-suited to this purpose?

Thanks ahead for any suggestions. :)

And when I took my tech tests back in 1976, I got correct just one more
than the minimum required questions, and did better on the 5wpm code,
receiving and sending. At the FCC in NYC. I thought i'd ace the
written and barely squeak by on the code. Did a lot better when I took
the (at the time) advanced and extra writtens to get my "nickel" extra
upgrade, back in 2000.

All that "Bruce" could prove (assuming the quoted story has any truth to
it) that he did in fact upgrade to extra, but not that he got all the
questions right. Big whoop anyway...

With the radio shark, that jack is actually a headphone jack that
doubles as an external antenna jack. Sounds to me like the Pogo does
the same thing.

Electrical service grounding via water pipes is common and acceptable.
Quoting from the 2005 NEC, which is the standard used in many or most
jurisdictions in the US:

250.52 Grounding Electrodes.
(A) Electrodes Permitted for Grounding.
(1) Metal Underground Water Pipe. A metal underground water pipe in
direct contact with the earth for 3.0 m (10 ft) or more (including any
metal well casing effectively bonded to the pipe) and electrically
continuous (or made electrically continuous by bonding around insulating
joints or insulating pipe) to the points of connection of the grounding
electrode conductor and the bonding conductors. Interior metal water
piping located more than 1.52 m (5 ft) from the point of entrance to the
building shall not be used as a part of the grounding electrode system
or as a conductor to interconnect electrodes that are part of the
grounding electrode system.

I agree this is not a good solution for lightning protection.

73,
Gene

Very common for local code to overide this and for good reason. You never
know when a piece of metal pipe is going to be replaced with plastic so a
ground rod has to be used with the electrical service.The plumber dont know
it is being used as a ground. and the electrician doesnt know all the metal
pipe has been replaced with PVC.Ground rods are cheap and easy to install.

Perhaps I am over-analyzing it. Here's what I meant:

To make the antenna, a quarter wave section of shield is exposed, then inverted and pulled down over the outside of the coax jacket. If it's pulled down TIGHT, it has maximum length and minimum spacing to the part of the shield under the jacket, hence the greatest decoupling takes place, if I understand the principle of the antenna.

However, what I alluded to earlier was moving the end of the shield up and down as a tuning method. I said this because another poster said you tune the thing by changing the length of the coax section and/or the shield section; I was looking for a non-cutting method to change the length of the shield portion and merely pushing the end upward seemed to be viable. (I'm sure the shield is sufficiently flexible to allow this.) If the end of the shield is pushed upward, it shortens the shield and should shift resonance up.

So, I imagine I can cut the shield section for slightly more than a quarter wave, then tune it as I described. The upper section can be tuned with dikes and/or a soldering iron, as necessary.

I have 160 watts available. ... about 90 volts at the feedpoint, so a whopping 1800 at the end of the shield. (Might want to keep the mike gain throttled back.)

OR ... use a larger braid over a spacer of some kind and solder it to the coax braid at the feedpoint. The spacer could be a piece of plastic pipe slipped over the coax at the outset. Actually, the braid doesn't really have to be braid. It could be a piece of copper pipe. The tuning operation would need to be slightly different; I'll need to keep a few inches of the original coax near the feedpoint. I'll tune it by sliding the pipes and bunching up the coax at the feedpoint. Or tune it by adjusting the length of the center conductor element.

I wonder ... if the pipe were sufficiently large, it would tend to broadband the antenna. I know of this effect at UHF. How about 10m???

I'm looking forward to this. <g>

Thanks! I'll try to remember that. In the past RACES exercise, I was stationed in the City Health Department Conference Room, which is Downtown and practically under the local repeater towers. This is also why I was not TOO worried about obtaining a particularly high gain antenna, and was more concerned with being unobtrusive. However, inside that building, the rubber ducky antenna worked, but just barely, so I took the mobile antenna off my Tahoe and screwed it onto my HT, using an SMA to Coax adapter. That received much better, but was a little unwieldly, plus it puts a little more strain on the little SMA connector than I like. This little "TV Antenna Feed Line" J-Pole should be just the ticket for any situation like this in the future.

The M^2 website claims "Horizontal polarity permits a single HO loop to
pick up 4+dB of ground gain that verticals can't."

Can someone explain this ? I wouldn't have thought polarisation would
make any difference.

I modelled a halo and a j-pole , both at 5m. I got 6.83dBi for the
halo at 6deg, and 6.65dBi for the j-pole at 4.5 deg. Am I missing
something ?

Yes it does, solves some of the problem you have with the all coax type of sleeve antenna. stuff some pieces of styrofoam inside the pipe to center the coax. Wind a choke in you coax and it is a pretty decent antenna. Consider this, make the sleve out of 2 inch conduit, at the middle of the antenna put a cap on the pipe with a hole drilled to accept a mount for a whip, RS and truck stops sell these. Bottom end screws into a 2inch PVC pullbox, other side of the pullbox screws on another piece of pipe used as a mast. There should be enough room in the pullbox for the choke.

But then my dummy load will load up on all bands.

The question is, in what direction(s) and elevation angles will it radiate on each band, and are those directions in which you want to talk with someone?

Tell me the loop configuration (apex up or down), where it will be fed
along the circumference of the loop, local geography, nearby
structures, ground conductivity & height above ground & I'll give you a
rough idea.

Do a search for the Big Wheel. It is a three element loop style antenna that looks a lot like a three-petal clover leaf. There is quite a bit of information on the Web for them.

Another source for a more conventional horizontal omni is KB6KQ. I have one of his 6m loops up and it has done well. It would benefit from being higher, but that's my fault.

John,
There will be some interaction.
One small point. You will need to resonate the longest loop first and then
so on.
Another point , for 4 loops , you could use a stacking harness such as would
be used to stack 4 yagi beams . Then go from it to the 1/4 wave matching
sections. Just a thought.
Good Luck, Ace - WH2T

After reading your web pages I have begun to imitate your set up. I
will be using a 44 foot wire radiator. It will (is) angling down to
one of the ground rods. That will permit the tuner to be installed
inside the house. This set up is physically much simpler for me. The
tower is a crank-up/tilt over arrangement with no guys so the actual
rigging must allow for a lot of movement.

By no means am I attempting to trvialize your many comments but I think the situation is not so complex.

Consider that the FCC only has limited power to control AR. The AR radio spectrum will be there no matter what FCC policies are. As long is there are people who are fascinated by the science, and to whatever degree they are capable of manipulating it, transmissions will take place on what is now the AR spectrum, even if the FCC were to "declare" an end to the service tomorrow. A better question might be what is the FCC's role in AR in the future? To what extent will those interested in radio allow the FCC to regulate them?

There will always be people communicating on the resource, legal or illegal. AR got its start without benefit of an FCC and it would continue to go on without an FCC. (ex. CB, the geeks using pringles cans for 1.4 GHz antennae, firmware patches to increase the power of there wireless routers etc.).

Getting young people interested is not a very relevant issue. The relevance of radio to them is important. On the island of Cuba we still have hams sitting at their keys in train stations communicating on 40m to South Florida on CW with equipment that is obviously very crude. For them it is fun...and relevant to them especially if you send them a few dollars. Young people and old who have attended basic physics class in high school already know that the HF/VHF etc. frequencies are there to use and they will be used whenever communication becomes relevant to their personal lives. Hell, even high school dropouts consigned to driving trucks for a living know all about 11m.

You cannot bring the relevancy to them; relevancy will find its own path, perhaps by people who today have no desire to participate in the traditional AR service.

For technology, I would not expect any miracles soon (despite all the former promises of smart new blood being able to enter the service after CW is gone). The physics of the natural resource is very limited. The bandwidth of "HF" is much too narrow for anything other than CW and AM radio to be used on a practical basis, no matter how good the propagation conditions. HF is a narrow creek, not a raging river whose energy can be harnessed for much more noble uses.

Finally, the FCC not only lacks effective control of the USA "amateur" community; US citizens interested in using the resource will do so with or without the permission of a government agency (as in Cuba and everywhere else for that matter). There is a large installed base of amateur equipment that will be used; there is a larger base than can easily be contructed using readily available components if the desire is there because some

condition in society made it relevant to do that. The existence of this equipment (and ready capability) lets allows others to assume that if they get on the bands, they will always have someone to communicate with.

Neither the FCC nor the ARRL had much influence on the number of people interested in the science today. They are neutral parties no matter what such organizations would have you believe. They react to society's conditions; they do not drive either the size of relevance of amateur radio to its practitioners.

Without an installed base of equipment, or easy availablity of components from which to make a radio, there would be no ham radio, legal or not. But the base is there and it is irreversible. With this base there will always be "ham" radio, legal or not, as there was ham radio before the FCC was formed in the '30s and as there would be after.

Additionally, the FCC has no jurisdiction at all outside of our borders so obviously it would take more than the FCC to end ham radio; it would take a UN treaty, and even then it wouldn't work.

So, ham radio will always be with us in some form or other, and operating as best it can within its natural limitations and manmade interference. Man is a social animal and will always want and need to communicate.

The FCC trying to regulate a natural resource is similar to the Fedreal reserve attempting to regulate the economy. It has some effect, not always as intended but with or without a federal reserve, there will always be an exconomy, for better or for worse. And I would not assume "worse" without the Fed..

Radio will always be interesting to some and that fact alone will always keep it alive. I think you flatter the service by assuming that the FCC or licensed radio amateurs have so much control over a sprectral resource that in the end cannot be regulated anymore than gravity or relativity.

Or, just lengthen it out to a full wave dipole, provide a matching
circuit of your choice, add a 1:1 current balun and end up with a MUCH
more desirable antenna ...

Oh yeah, you still can use the ne-2 bulbs at either end (or both) of
this dipole and end up with that kewl "cb look!" <satisfied look>

I doubt if the FCC cares about what we do inside our allocations. It is my opinion that if we want to keep our bandwidth we must remain a self policing group. The last thing we want is for the FCC to ever have to clean our house, I am afraid they would do it with a bulldozer.

That's a clever idea. I am recalling four turns as the spec for the
feedline choke at 2m. However, at 28 MHz, there's a lot less inductive
reactance in those same four turns. How many turns are we looking at for
the choke?

What you need is a turnstile antenna. And you could mount it partway up the mast and keep the vertical antenna, as far as that goes. I'm not sure if any manufacturer makes these for 2m, and it's a bit of a chore. Essentially you put up dipoles at right angles and feed them 90 degrees out of phase (in phase quadrature). You get horizontal polarization at the low angles and pretty much omni pattern. Polarization turns circular overhead, though (not necessarily a drawback for space work).

Gary,
There were some product reviews on eham:
http://www.eham.net/reviews/detail/500 Some of the positive commenters
provided links that detail their installations...
W7IS: http://journals.aol.com/w7is/GlenMartin26ftTowerInstall/
N8XE: http://www.qsl.net/n8xe/radio/tower_project.html
You might want to read *all* the comments before you place your order.

73,
Bryan WA7PRC

Hi Brian,
The explaination has to do with ground reflection gain that a vertical
signal does not "have access to".
Of course a horizontal dipole would have this same increase in gain, so it
isn't really a meaningful measure.

There was a time when the expression "water pipe ground" was common.

Extra ground rods actually contribute to the risk unless the are tied
together with at least #6 wire. (NEC) Allowing the grounds to be
commoned through the power distribution will put appliances in the
loop with expensive results.

My modelling shows similar ground gain, but it does assume the
reflection coefficients are the same for both senses of polarisation.
This could be it

REAL desperation is having to keep four or more dialup accounts active
because of having lost so many due to stupid blunders.

Yep, that why we use "grounding" and "bonding" and why work should be
done by a certified electrician. Grounding should be taken back to a
single point so you dont get loops running through expensive
appliances.

Jimmie

Right. Just like they cleaned up the 11 meter band. FCC is powerless against people who choose not to obey them. True, they can pick-off offenders one at a time. But as with CB, they would be powerless against an installed base of operators who wish to transmit. Any interest group that obtained todays amateur allocations would be subjected to massive interference by illegal operators rendering their resource financially useless. And how would you expect the USA FCC to "clean up" the CEPT countries? Or South America? Or Canada? Japan? China? etc..

Yanno, why does the 11 meter band need "cleaned up?" I kinda like it
the way it exists. Reminds me of a "Mad Max Movie", I just end up
wondering when Mel is gonna show up?

11m does not need to be cleaned up. It is what it is. One might say say the
the 11m operators are similar to ham radio pre-FCC. With their huge
installed base they cannot be cleaned up. For the licensed amateur bands of
the future, it is simply a matter of how much regulation this group will
accept from FCC's Riley et al,. Actually 11m have formed their own self
policing faction being far more mature than many of our own 20m classes,
even if "illegal" by technicality.

ml wrote:
> interesting , resonant too hmm wonder how the waves look on that dipole?

The free demo copy of EZNEC available from www.eznec.com will
display the current waveform. Here's a copy of a posting I made
to eHam.net

The following results are approximate but show the resonance trend on
80m Vs dipole length. Take a certain length dipole and adjust the length
of the 450 ohm ladder-line for resonance on 7.15 MHz. i.e. NOTE: All of
the following antenna systems are resonant on 7.15 MHz. and cover the
entire 40m band with an SWR of 3.5:1 or less (good for built-in
autotuners). Here are the approximate results:

dipole length : feedline length : resonance on 80m

170' : ~85' : 3.62 MHz (3.52-3.72)

160' : ~87' : 3.7 MHz (3.6-3.8)

150' : ~89' : 3.8 MHz (3.7-3.9)

140' : ~91' : 3.92 MHz (3.82-4)

130' : ~92.8' : 4.06 MHz (resonant out of band)

120' : ~94.7' : 4.23 MHz (resonant out of band)

Yesterday I had a 130' dipole that exhibited the above characteristics.
I have changed it to a 144' dipole and now, with one length of
ladder-line, the antenna covers all of 40m and 200 kHz of 80m using the
limited range autotuner built into my IC-756PRO. A bonus is that the
autotuner also tunes this fixed antenna system on 30m and 17m.

The reporter asked Colin Powell (or George Bush), "What proof do you
have that Iraq has weapons of mass destruction?"
He replied, "We kept the receipts." -- Bill Hicks

"They thought I was fair game. I was an instrument of purpose to achieve
their desires and not 100 percent real and ALSO that they had me by the
short curlies because I thought that the world revolved around them and
therefore I think that I am fair game and rightly so. If they want to
play dirty, I get to too. It's not a one-way street. I will use the
physcial strength that I have over them, my superior 5'7-3/4" height
advantage, the boxing moves I paid to learn, the suprise of pussyfooting
up to them with their back to me in a public place 18 1/2 years after
the fact and thus not only do will they not know that I am but a pica's
distance away from them, but that I even exist on earth." -- Chris Tsao
is secretly John Wentzky's psychic twin. MID:
<1161246083.152300.195760@m73g2000cwd.googlegroups.com>

Looney Maroon nominee for August 2006 Johnny D Wentzky foamed:
"You never asked someone who goes into areas of the internet that are
only for adults who has an underage id somehow or another if they are a
cop posing as an underage person online?

I guess lots of people just don't watch dateline or read stories much. Why don;t you go to pervertedjustice,com and see what they do. They are awash in their self-proclaimed glory after they lied to membners of the public.
They are awash in their self-proclaimed glory after they posed as an underage person and agreed to do all sorts of sex acts wioth adult males, and they are adults posing as teenager themselves. They make themsleves into liars by falsely impersonating underage persons and by not fuilfilling the words they tell the victims online in their chats. Why don't you read it where they tell these victims of their deceit about how they have been with grown men and such? Why don't you read it where they say, "That would be cool." after someone makes an advance towards an adult who is posing as a teenager? And, where they agree to meet the person, etc.
Lost control, didn't you?
Is that why you feel as if you need to lie so much now? I see where lots of these false impersonation games are not sticking. They feel as if they can lie and then order the victims to get counseling in the gayblade, governmental, pro-choice tax leech counseling centers. They are doing nothing more than usury and fraud in many cases." -- Wentzky almost comes out of the closet as a pedo/ephebophile in MID: <H%%Eg.28916$Uq1.22411@bignews6.bellsouth.net>

To the moron that is flooding all of Usenet with these "M15" posts:

You may very well have a valid political viewpoint and reasons to complain, but your spamming newsgroups in which it is off-topic is NOT winning you any support. Neither is your making more than 4 or 5 posts a day to groups where your subject is relevant.

KNOCK IT OFF, JERK!

You are NOT serving your cause at all by annoying people. You will be IGNORED, and you will be reported to wherever you post from and lose your accounts, just as trolls and crackpots do. If you are serious, act sanely and be courteous to others!

106. GO AHEAD, you can transmit voice SSB NOW!

NO NEED for a report and order on the fr.

Since the FC already publically announced the acceptance of no code, that effectively permits anyone with a CSCE for general or technician class element 2 CSCE or license to use HF SSB NOW in the permitted frequencies.

There is no statute that requires publication in the FR before a requirement is effective, only that the regulating agency agree in principal to the new requirement. Such a statute would obviously be unconstitutional. It is merely a government formality which cannot be enforced by the courts.

The FCC did not publish an effective date nor did they choose to publish one in the federal register. That means you can transmit SSB voice at this very moment.

Go ahead element 2 or 3 CSCE'S or tech license holders, you can transmit NOW! I look forward to seeing you on the bands (though I do spend a lot of time in the CW portions).

no mere elelment 2 CSSE wopuld cover that the element 2 test gets you
a tech license the only people a new element 2 csse would affect would
be a novice and and there are damn few of them and fewer still that
are both alive active and still in radio

I agree it would be difficult for the FCC to enforce the old rule and
prevent me from operating on 10m right now but Hams would do so most
likely

Here is the text: The R&O is ALREADY adopted;

Before the

Federal Communications Commission

Washington, D.C. 20554

In the Matter of

Amendment of Part 97 of the Commission's Rules

To Implement WRC-03 Regulations Applicable to Requirements for
Operator Licenses in the Amateur Radio Service

Amendment of the Commission's Rules Governing the Amateur Radio
Services
)

)

)

)

)

)

)

)

)

)

)

)

)

WT Docket No. 05-235

RM-10781, RM-10782, RM-10783,

RM-10784, RM-10785, RM-10786,

RM-10787, RM-10805, RM-10806,

RM-10807, RM-10808, RM-10809,

RM-10810, RM-10811, RM-10867,

RM-10868, RM-10869, RM-10870

WT Docket No. 04-140

REPORT AND ORDER AND ORDER ON RECONSIDERATION

----------> Adopted<---------- : December 15, 2006 Released:
December 19, 2006

By the Commission:

And,

Generally, the NPRM proposed to eliminate the requirement that an individual must pass an international Morse code telegraphy examination in order to qualify for any amateur radio operator license.

As discussed below, ---------->this R&O implements<----------
the proposals set forth in the NPRM. Specifically, we will amend our Amateur

Radio Service rules by:

. revising the examination requirements for obtaining a General Class or Amateur Extra Class amateur radio operator license; and

. revising the operating privileges for Technician Class licensees to include the operating privileges that are authorized to Novice Class licensees.

So go ahead and transmit!

I doubt it. Until it shows in the Federal Registry, the old rules are
still in force. And then the old rules stay alive until 30 days elapses.

Besides, if all someone has are CSCEs, they don't even have a callsign,
so how could they operate?

And those CSCEs will NOT be accepted for processing for the upgrade until
the effective date listed in the Federal Register. So if the CSCE expires
before that effective date, they will have to retest.

Subject: newsgroup fa, net, etc.

Won't we need to change the .ngfile also? Also is ALL an
acceptable newsgroup
on the left side of the dot such that ALL.ALL will catch
everything?

Rusty is right (or is that "Rusty is Wright"?) - we have ALL in our
.ngfile
so I tend to forget this. ALL.ALL may or may not work, but ALL
certainly does.

Mark

I plan to make the change on Tuesday unless something horrible happens.

Apparently nothing too horrible happened after they changed the .ngfile

because we're still pecking out our little newsgroup messages all over the world 24 years later.

Gosh I hope not....

btw these new 300baud modems are lightening fast, huh?
But you need 256kb of system ram to use them, my box only has
128kb, darn.

Mark,
Yes, the .ngfile needs to be fixed and maybe we should use .net instead

of .ALL, talk to the guys and let me know what you think.
By the way, my friggin 8-track just went out in my pinto so i think i'm

going to pick me up one of those new Casset Tape decks. Those things are outta sight, I hear Rick James has one! He's my hero, anyway get back to me soon on that other stuff.

Brian

Yeah, but it's not the oldest one on the net. Look at this site:

http://communication.ucsd.edu/bjones/Usenet.Hist/Nethist/0061.html
The earliest post at that site is from May 27, 1980

Lots of other ancient stuff on there too...

Drew

Hope I didn't do that!

Perhaps but a license upgrade on paper is an administrative exercise subject to the administrivia that you mention. In this case the bureaucracy may not (yet)properly reflect the law..

On the other hand, the legality is defined by the adoption and release dates of the Report and Order that adopts the NPRM. The R&O was released on Dec. 19 but was actually effective on the adoption date of Dec. 15 2006.

Legally, Part 97 does not state that you must be a general class or technician etc. to transmit on certain bands. It merely states that one must pass element 2 to transmit SSB on 10m segmets, element 3 to transmit SSB on

other segments etc.

The license itself only reflects what the law requires (this may be an exception as you point out). The law governs who may transmit where and what element credits must be obtained before doing so.

However, actual statute law trumps bureaucracy. The Federal Register merely records laws that have already been enacted. The Constitution was in effect prior to the existence of a FR and nowhere is the FR mentioned in today's constitution.

SNIPPED

100% WRONG!!!!!!!!!!

Any law or regulation in the USA becomes effective ONLY after it is PROMULGATED!!

For laws and regulations at the Federal Level that PROMULGATION only occurs in
the Federal Register.

Operate prior to that date at your peril.

/s/ DD, W1MCE

118. Re: GO AHEAD, you can transmit voice SSB NOW!

Newsgroup: rec.radio.amateur.antenna

Jim's caution below is accurate.

Until the effective date of the new rules, you can't upgrade to General or Extra without credit for Element 1.

AFTER the effective date you CAN upgrade to General or Extra without having passed Element 1.

HOWEVER, you MUST upgrade by either presenting valid, unexpired CSCEs for the written elements for the class of license at a VE session (and pay the fee ...) OR take and pass the required written elements (and, again, pay the fee ...) at a VE session.

Please do NOT operate beyond your license privileges.

73,
Carl - wk3c

Most Definitely!

Hi Carl - Haven't heard from you for quite a while. Hope all is going well.

Someone keeps posting this kind of stuff, I can only imagine that they
want to scam people into illegal operation, then hoping they get caught?
It's a funny world we live in.

Despite my personal preferences for some sort of Element one testing,
(heck, I would prefer shrimp, steak and and lobster every evening too) I
am kind of excited that there will be a crop of amateurs, new to HF,
that will need a good deal of Elmering. Lots of exciting stuff to learn
and pass on.

And rule number one is what you stated above - keep within the privileges.

120. help with mounting on-glass ant on 2005 Toyota 4Runner

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-05 21:40:31 UTC
From: Scoot <Scott.Kawahara@gmail.com>
Message-ID: <1168033230.967332.300700@s80g2000cwa.googlegroups.com>
Source record: 47184

Hi Gang,

Could someone help me with advice on mounting an dual band on-glass antenna on my 4Runner. I have heard that you cannot mount on-glass antennas on auto-glass with metal in them, so has any one else mounted a on-glass antenna on their 4Runner of similar year? I guess I don't want to use a trunck mount since it will dig into the paint on the underneath of the trunk and I will get rust with the salty Hawaii climate. Any suggestions?

Aloha and 73,
Scott

Happy New Year, Cecil. Really neat design. Can you describe the
balun you used?

Thanks,

Jim, AC6XG

When one feeds the antenna system at a current maximum point, the balun is non-critical. I am presently using ten turns of RG-400 on an FT-240-61 toroid with no measurable common mode current on an MFJ-853. As you know, the stress on the balun is reduced when the resonant current maximum point is located at the output of the balun-choke. That's another bonus for the matching system that I use.

On glass antennas are fine, not as good as an antenna in the middle of a metal roof, but make up for not having to tear half of the interior loose (I've installed many of these antennas on our commercial fleet over the past few years). You are correct that any metalized coating of the glass will diminish or prevent transfer of energy from the inside box to the antenna. The installation instructions warn against installing on metallized glass or mounting over defroster strips.

The question is whether the windows on your 4 Runner are metalized.

Another option is a magnet mount on the roof. About a year ago I got tired of my Larsen 2m/440 colinear getting knocked over going in and out of the garage. I looked around and bought a Pro-Am MO144-440 which seems to be a 1/4 on 2m with a center open air coil for matching on 440, I assume. I don't travel extensively so it works well for my purposes.

Mike, forgive me for being blunt but you are in fantasy land.

It didn't happen when we reduced from 13 wpm to 5 wpm. What makes you think that reducing from 5 wpm to 0 will have any effect?

I too have said I was waiting for the long promised injection of scientific RF talent and youth into the service but I was merely being cynical because it was a false promise 10 years ago and its non-fulfillment in coming years will prove that the premise was false; it was merely used as a talking point to support no-code and the FCC bought off on it.

Of course, and as is the case for so many political matters, truth is not really that important and there is no accountability for these false promises except by pests like me who will use every opportunity to remind us of them.

Hi Cecil,
It seems like it's been a decade since we debated on RRAP. I hope all is well with you.

I plan on erecting a multi-band inverted V with several insulators and associated shorting connectors along each leg so that with all connectors open, the antenna is resonant on 10m; with the first insulator on each leg shorted, the antenna is resonant on 15m; with the first and second insulators on each leg shorted the antenna is resonant on 20m; et cetera. Shorting and opening insulators is easier than winding accurate chokes!

For a balun, I'm considering N4UJW's "Ugly Balun"
(see http://www.hamuniverse.com/balun.html).
UJW leaves the diameter of the coil form to the reader, only specifying that 18-21 feet of coax be used. Can you (or anyone else on RRAA) tell me if there is an optimum diameter, considering that most of my operations will be on 20m?
(On that page, UJW has two balun projects -- see the first one.)

Warmest regards,
Jeff KH6O

This subject was recently beat to death over on QRZ.com or
eHam.net, I can't remember which. Here's some actual
measurements showing how the choking impedance varies
with frequency:

http://www.k1ttt.net/technote/airbalun.html

An ugly balun (N turns of coax) will not cover a 10:1
frequency range very well. If it performs well on 10m,
it doesn't have very much choking impedance on 80m. If
it performs well on 80m, it will have reached its series
resonant low impedance point before it reaches 10m. An
ugly balun performs reasonably well over a 3:1 frequency
range. And the choking problem worsens considerably with
non-resonant antenna systems.

However, the necessary choking impedance is minimized
if the antenna is low impedance resonant as yours will
be. I made some measurements on 20 turns of coax on a
2 liter pop bottle. It was parallel resonant at 14 MHz
(good high impedance) and series resonant at 28 MHz
(bad low impedance). It would probably function pretty
well from 40m to 15m.

A toroidal 1:1 choke-balun is much more broadbanded than
an ugly balun. For your antenna, ten turns of RG-400 on
a FT-240-61 toroid would, like mine, be good enough.
The AB-240-kit contains that toroid and comes with
instructions for winding a 1:1 choke-balun, all for $9.
However, I would not recommend that balun for non-
resonant antenna systems where three of those toroids
stacked would be about right. That web page is at:

http://www.amidoncorp.com/aai_cost_experimenter.htm

How do you plan on actuating the switches? I tried some knife swithes and
thought I could switch them using a hook on a pole. This didnt work very
well for an all band antenna.

When I was in high school, I built my dipole with
a pulley at each end. For changing bands, I just let
the dipole down and either installed or removed the
jumper wires across the insulators. An Inv-V would
only require one pulley.

Yeah I thought about this but was trying to stay away from raising and
lowering the antenna. I used to have the antenna on a pulley but found that
sometimes the neighbor kids would lower it for me. The ones who were doing
it arent around anymore so I guess its safe to put it back up now.

hi

wanted to help a fellow ham set up an antenna on his terrace
it's kinda a best effort attempt naturally the building won't allow
anything 'outside' so he just has the confines of the terrace

the total length of the longest side of theterrace

about 15ft on the longest side so here is my question

i was going to use a sgc 237 as the dipole 'center' and extend the legs
from there

since the total space is short would it be more advantages to make the
leggs a coil like a slinky? will this be of any real benifit?

if so how many ''turns'' and how big dia each ''coil''

my other option was to mount the sgc on the center of the celing extend
the dipole horizontally about 7ft each side then down to the floor
vertically like upside down U

i wondered how a loaded verticle would be or even using a verticle whip
into the sgc because i am not shure how i could make a 'radial'
/counterpoise

i'd like to give him at least 40m to 10 i realize that the sgc
really can 'tune ' anything but if it's too far outa wack (away from
resonance etc) it would just work poorly

he put up a glass metal framed enclousure around the terrace the metal
is isolated but a strange shape for an antenna i could try to load
that perhaps using a wire around his apt as the counterpoise? would
this be effective?

he's up about 20 stories on a high point everything elese is lower far
as eye can see to the horizon

any help is surly appreciated he's an old timer that wants to get back
on the air

ml

Hi there,

I have some CONIFER MMDS antennas into my shack
these aeriel have some internal circuitry that seems to be ...
downconverter ?
I would like some info about their reception frequency (heard about...
8Ghz ??), I guess their output to a TV set is in the VHF hi/lo band ?

If I connect these antennas to my ICOM ICR-7100, what kind of signal
could I get ? Could I catch some ships radars , or Wi-FI signals ?

Thank you

Most of the MMDS stuff I had back in the early 1980s took 2.1 GHz in and put out on channel 3 (TV) to pick up HBO when they used to broadcast in the bigger cities without encryption of any kind. You might be able to use it on the 2.3 GHz amateur band and an IF of 144 MHz (after figuring out the LO frequency of the converter).

I would be inclined to lay down as large a ground plane as
possible, i.e. floor the terrace with hardware cloth. Then
put up the longest possible center-loaded vertical in the
center of the ground plane. He has many of the same
constraints as a mobile antenna.

150. Trap dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-07 01:22:59 UTC
From: Nate Bargmann <n0nb.DO.NOT.SPAM@ME.networksplus.net>
Message-ID: <obCdnUWKK4vu1j3YnZ2dnUVZ_qDinZ2d@bluevalley.net>
Source record: 47214

The past couple of days I've been reviewing literature on trap dipoles. My goal is to build a Field Day dipole for 40, 20, 15, and 10 meters (the club already has 80m covered). For simplicity of operation, I want to avoid an outboard tuner. So I'm considering a balun fed dipole that can be trimmed up at the band edges with a rig's built in tuner if necessary. I also want to avoid the patterns that occur on the upper bands with a longer wire (I have looked over W4RNL's 44 foot multibander with interest, but the high impedance on 15m requires a ladderline feed and a tuner, so I've discounted it for this project).

So, I'm left with two practical alternatives, a fan or a trap dipole. From reading this group's archives and various web pages, I've come to the conclusion that while the fan dipole is simple to construct it is susceptible to element interaction and may require additional support or care in element spacing and antenna erection. These points seem to weigh against it for a quick and nearly fool-proof antenna for Field Day/event/emergency use.

That leaves me considering a trapped dipole. In this category are traps using an inductor and capacitor and those made from coaxial cable. W8JI has documented just how poorly these traps will probably perform compared to those made of discrete components. However, given their (apparently, as I haven't tried to build any yet) low cost they may perform well enough.

More research has uncovered that suitable capacitors and inductors are hard, if not impossible, to find and when procured the parts may cost as much (more?) as the Reyco traps offered by Unadilla. Perhaps decent performance does have its price and the price for three pairs Unadilla traps is reasonable for the simplicity I desire.

I guess this is a long and rambling post to get to the point that the trap has become sort of a historical device in modern amateur radio antenna implementations except for commercial yagis. For the record, at my home QTH I use a center fed Zepp style antenna with a tuner, so I'm not averse to that concept, I just want to avoid it with this special project.

Despite the lack of literature, are there some trap projects that are easy to build, but perform better than coaxial traps? I must admit that I'm not to good at scratch building things as I'm better at fixing stuff or following a pattern than spending a long time experimenting.

I know this is long, but I wanted to share my thoughts to show the track of my thinking on this.

73, de Nate >>

Hi Nate,

No more than trapped dipoles and in real comparison, probably less. No
antenna is tuned and put up working on the first attempt unless it is
a 2M ground plane at 30 feet. ....you are not describing that.

Given your hemming and hawing about parts cost, and willingness to
suffer what Tom describes as poor performance from cheaper components
- what's the problem?

While there's bound to be *some* interraction, there are construction techniques that make additional supports unnecessary...
TV ribbon cable or "window" ladder line can be used to get elements two-at-a-time. IIRC, the latter type can be found w/ copperclad steel conductors (for mechanical strength). To get more bands, you can add more parallel lengths of either line by using cheap/easy-to-make looms. This method has been described in many ARRL Antenna Book & Handbook.

I've not tried them but others report favorable results. I've seen online Javascript calculators that will get you close. The biggest drawback IMO is that there's no easy way to adjust the resonant frequency.

I've made trap dipoles (80/40m) from scratch. Sure, to keep losses lowest, ready-made air inductors are preferred. But, Barker & Williamson or Air-Dux inductors aren't cheap, so I've "rolled my own" using PVC plumbing parts as forms/insulators. You'll find HV transmitting capacitors equally expensive. But then, a short stub of coaxial cable works as a capacitor (~30pF/ft). If you initially cut the stub longer than calculated, you can trim it up to the operating frequency with a pair of wire cutters. Tip: to prevent arc-over when using high power, trim *only* the outer jacket/shield. Some noncorrosive RTV seals the coax when you're done. A grid-dip meter is a handy tool for adjusting the traps... but not *absolutely* necessary.

Hardware cloth is a wire matrix where all the wires
are soldered together. The openings are square and
about 1/4"-1/2" on the sides. It is commonly used
for small animal cages. I'm sure you know what it
looks like, just not familiar with its name. It makes
a better ground plane than chicken wire or hog wire.
It also makes a good top/end hat.

Have you considered a horizontal loop fed with the SGC? At 20 stories,
it ought to be quite a performer. I assume the circumference of the
terrace is about 45 feet. The metal frame you mentioned could be a
problem, but it is a fairly costless and quick option to try.

Chuck

There is also expanded aluminum mesh (don't know if you already gave a url with it.) A friend gave me a load of this stuff, he works in demolition of buildings. The stuff was used in stuccoing buildings. All I had to do was go to his yard and persuade the mesh out of the stucco with a hammer.

Problems I ran into was soldering it together, soldering aluminum takes quite a bit more skill than copper!!!

He might try a horizontal loop. Just run a wire around the perimeter as high as possible, with as large an area as possible. Then feed it with open wire line, or a short coax into the SGC tuner. At 15 feet per side, it should be good down to 20 meters, and with some lower effectiveness at 40.

167. Followon to image theory

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-07 19:17:55 UTC
From: David <nospam@nospam>
Message-ID: <6bWdnef-Z67F2jzYnZ2dnUVZ8tqqnZ2d@bt.com>
Source record: 47081

Various books claim that a ground plane reflects the radio wave emitted by the vertical, and then claim that a ground plane is formed or simulated by four elevated radials.
I emailed two Professors of antenna theory about this.

Reply from Professor Constantine Balanis:
"The radials should act more as a ground plane. Four of them are usually the minimum. The more of them, the better the ground plane. The objective of the ground plane is to reflect the energy from the main element; the vertical wire".

Reply from Professor Vincent Fusco:
"My view would be that the radials form an image plane, the radials themselves do not radiate".

The following link on Navy Training Series show the radials as reflecting the radio wave and forming an image antenna:
http://www.tpub.com/content/neets/14182/css/14182_219.htm

Quotations from books below.

Antenna Theory third edition by C.A. Balanis page 205 "Improvements in the efficiency can be
obtained by placing radial wires or metallic disks on the ground. [New paragragh] The analytical procedures that are introduced to examine the ground effects are based on the geometrical optics models of the previous sections. The image (virtual) source is again placed a distance h below the interface to account for the reflection."

Antenna Theory third edition by C.A. Balanis page 511 "To reduce the wind resistance, to simplify the design, and to minimise the costs, a ground plane is often simulated, especially at low frequencies, by crossed wires as shown in Figure 9.11(b). Usually only two crossed wires (four radials) are employed. A larger number of radials results in a better simulation of the ground plane."

Antenna Theory and Design by Stutzman and Thiele page 198: "A ground plane can take many forms, such as radial wires around a monopole, the roof of a car, or the real earth....The pattern of an antenna over a real earth is different from the pattern when the antenna is operated over a perfect ground plane. Approximate patterns can be obtained by using image theory. The same principles discussed in Sec 2.3.1 for images in perfect ground planes apply, except that the strength of the image in a real ground will be reduced from that of the perfect ground plane case".

Antenna Theory and Design by Stutzman and Thiele pages 66 & 67: "The principles of image theory are illustrated in this section with several

forms of the monopole antenna. ... Figure 2-12(c) Practical monopole antenna with radial wires to simulate a ground plane".

Antennas for all applications third edition by J.D. Kraus page 719: "In Fig 21-9d the solid-sheet ground plane is replaced by 4 radial conductors. Fig 21-9(d) stub antenna with 4 radial conductors to simulate a ground plane".

Antenna Engineering Handbook by R.C. Johnson page 110: "The geometrical shape of a sleeve antenna, or a sleeve monopole, is sketched in Fig. 4-22a. If the image of the structure is included, then we have a sleeve dipole as shown in Fig. 4-22b". Figure 4-22a shows a coax cable with the centre wire going upwards forming a vertical element, and the braid being connected to a ground plane. Fig 4-22b appears to show a dipole being formed from a monopole and its image antenna.

Foundations of Antenna Theory and Techniqes by Professor Vincent Fusco pages 190 and 191. Claims that image theory i.e. image cancellation applies to the horizontal section of an inverted L antenna. The vertical part of inverted L antenna is a short monopole i.e. less than a quarterwave long.

However references against this are below.
Antenna Engineering Handbook by R.C. Johnson page 118: "When the ground plane is of finite size, the image theorem does not apply."

Professor Douglas Miron in his book Small Antenna Design says that the vertical element is driven against some horizontal elements. The horizontal elements have canceling fields. He says that the radials are an artificial ground called a counterpoise that also radiates.

Various books also say about using image theory to analyse corner reflector antennas.

RF experts appear to disagree with each other over the vertical monopole with quarterwave radials - Roy Lewallen and Professor Douglas Miron versus Professor Constantine Balanis and Professor Vincent Fusco.

I have two 10' sections of 25G where the spacing
between posts is the specified 11.25" at the bottom
but is only 11" at the top. These sections will not
fit together. Does anyone know anything about 25G
sections with 11" spacing between the upper posts?
The 11" spacing is too precise to be an accident.

[big snip]

David,

The images in these cases are not real. That's why they are called virtual. However, real or not, these images can provide useful assistance in simple determination of the expected radiation patterns. Like most models, the image model has limitations. Some applications will succumb to image modeling more readily than others.

Bottom line: There is no real conflict among the experts. Image modeling is generally quite easy. If the results make sense, be happy. If not, then try more complex methods. I would expect all of the experts to agree that detailed mathematical modeling is required for the best accuracy unless the image model has unrealistic parameters such as infinite extent, perfect conductivity, etc.

Hi David,

This is becoming tiresome by half.

"Quotes" that do not have a context (what was the question asked?) are more name dropping than an informed discussion. It is also called shopping for testimony.

"Does a ground plane reflect?" This is a loaded question much like "Have the Republicans offered a balanced budget?" Each question can be so heavily qualified as to guarantee success and bragging rights. Each can be so heavily doped up on the narcotic of self-indulgence as to offer only the prospects of a somnambulistic nod of affirmation.

If one conspired to erect a 2M vertical on the radial field of a former AM station; then, yes, these radials reflect admirably. If one takes the same 2M vertical (as shipped from, say, Comet) and looked at the reflection components of its radials; then, yes, these radials reflects, but with less than pedestrian results. Difference is found in the application. The AM station ground field will produce more 2M reflection contacts to the horizon, the standard radials of a 2M Comet will have indifferent reflection contacts oriented towards satellites.

Simple modeling and analysis reveals this in less than an hour's work.

More effort in the field confirms the modeling and analysis.

Modeling and analysis conform to every expectation offered by all the authors quoted, given they use the same tools and were, perhaps, instrumental in their development.

The "Image" theory relates to reflections found in the far field beyond the physical extent of practical radials. To force the

standard implementations of radials into supporting this theory (to the exclusion of the greater application), debases the intent of the theory. Actually, to call it a theory is painting the rose and gilding the lily. This tarted up observation is used mainly to soothe the troubled minds of neophytes until they become accustomed to dealing with larger, more involved problems. It is a suitable metaphor; however, metaphors are the weakest form of argument as they often fail early on close examination.

Hi David,
What does Aristotle have to say on this subject?
Quoting from authorities may have been good enough for the ancients,
but it doesn't have much value here. You have to descend one
level of abstraction down, and use what you should know about
electromagnetic theory in order to understand what's going on
here. If you did, I don't think you'd see any serious
disagreement between the people you've quoted.

No real big problem, just feeling out the group for any other ideas of trap construction that my Google searches haven't revealed. That's all.

I've found more on coaxial trap design including VE6YP's Coaxial Trap program. I have studied W8JI's material more closely and I see that he found that the traps have lower loss above the design frequency than at it. This would suggest that a 10m trap might be better implemented at a design frequency of 27.5 MHz than 28.4 MHz.

I think this is what I'll shoot for.

Sorry Nate,

I don't follow the logic of this at all. Are you expecting the trap
to cut off all frequencies above 27.5 MHz?

good idea technically speaking but i don't think i'll be able to hide
anyof this stuff in his apartment

if i go verticle i'd hope maybe to hide 2 counterpoise"" like wires
around the far walls but certainly not mesh

the only way i could think of using mesh is around the railing of the
terrace hanging it verticle and putting the verticle antenna part
ontop(higher)
the railing is concreate

You really need to have a man to man discussion with the seller of the tower sections.. Start by marching into his establishment and firing a couple of rounds of Colt 45 into the ceiling... This will set the tone for the discussion to follow...

FWIW I've made multi-band trapped dipoles in almost the same way;
however for the feeder I used light[weight] co-ax [RG58} terminated in
a 1:1 balun wound on a toriodal ferrite [IIRC, Phillips 4C6 material].

For tuning the traps, I jigged up an SO259 socket on some paxolin
board. The connection from the SO259 center conductor went via a 28v
light-bulb [voltage not critical I guess, but it's what I had] to a
flying lead terminated in a croc-clip., likewise the return to the
SO259 body via a flying lead and croc-clip. The coil/ co-ax capacitor
parallel tuned circuit is thus connected, in series with the
light-bulb, to my TX [IC735, on lowest power]. The resonant frequency
is indicated by ther light-bulb going dim or out altogether. Tweak coil
spacing/ trim co-ax capacitor to suit. Crude but effective.

The Technician license was and is a dead end. Lots of people talked
their only mildly interested spouses and friends into it. It was a mistake.

Notice that you speak of Talent and youth. I don't particularly
careabout either - note I spoke of inexperienced people, not
Techno-wizzes or youth. Techno-wizzes already know it all, and the days
of youth involvement in Amateur radio as well as many other hobbies is
pretty much over. Youth are being largely segregated from the rest of
the population, presumably to "protect" them.

Sigh... Sometimes I am amazed at the stances taken by some pro-code
people. And this is coming from a pro-code Ham.

At least you can be thankful for the many years that Morse code testing has ensured that Hams of old were upstanding, technically savvy and morally upright. ;^)

I got them for $20 each used from an individual ham in
AZ about ten years ago. Don't remember his name or call.
I think I can use a car jack to bring them back to the
specified spacing. I should have tried the fit while
they were on the ground rather than 40 feet in the air. :-)

Same thing happened to me this summer. I put up 4 sections by myself and it went fine. Then with some help on the ground pulling up the next 2 sections, the leggs did not drop in. I did not measuer them but the leggs did not seem to match by a small ammount. I used a home made version of the Tower Jack to force the sections together and then pull them down to the bolt holes matched. Actually had to drill out the holes as they did not match exectally either. Not much off, maybe 1/8 of the hole diameter. Could not get the holes to line up even with a big drift or punch.

I have two sections with identical 11" spacings,
1/4" out of spec. It's too consistent to be an
accident. I wonder if a batch was manufactured
out of spec?

I expect that the support bracing is bent and if you straighten it the problem will go away. Sounds like someone was a little rough with these sections.

Nope, the bottom of the tapered section is the
specified 11.25". Somewhere between the beginning
and end of the 4" tapered section is where the
problem occurs. And two sections are virtually
identical which would seem to rule out any
accident.

Ah, this must be in the vein of "they have been unable to prove EMR
safe".

There are clear guidelines / rules on maximum permitted exposure to EMR
that should allow design and operation of a station with confidence that
it most unlikely to be an EMR hazard to one's self, family or the general
public. Understanding and applying this is just another facet of the
hobby today, though I concede it is beyond our new 6 hour hams (though
that is part of the reason for their low power limit, should they observe
it).

One of my current projects is a self contained field strength meter for
field measurement near a transmitting antenna. It consists of a small
single turn untuned square loop, terminated in a known load, a detector
and an inexpensive battery power LCD panel meter, all self contained
mounted on a non-conductive stick with no trailing wires. It is fairly
straight forward to produce an Antenna Factor / Freq chart using NEC, and
a detector calibration (Vout/Pin). Trials have been encouraging with good
correlation with expected field strength.

On the other hand, it has been demonstrated that UV radiation is a health
hazard, and there is no "safe" exposure level (ie a threshold below which
no changes will take place in living cells). If one took a balanced
approach, before becoming too concerned about EMR MPE, one would protect
one's self from ANY sunshine, direct or indirect.

If it appears that ham's brains have been addled by RF, they were
probably that way before exposure to EMR, it might just be a factor for
selection of hams. (You don't have to be mad to be a ham, but it helps!)

Owen

I've got an SG-500 between the IC756 and the antenna.
Coax out of the SG-500 goes to a 1:1 balun-choke and
then to the ladder-line.

The responses from the professors frankly baffle me. If that's what they said, and if they meant what you think they mean, then yes, I disagree with the professors. Folks will have to decide whether to believe them, or me, or learn more about antenna operation so they can come to their own informed conclusions.

I won't comment on the Navy training manual, recalling some of the simplifications made in the equivalent Air Force documents in an effort to make electronics understandable by the target audience.

Unlike low pass filters, traps do not have a low impedance
at lower frequencies and a higher impedance at high frequencies.
The impedance plot Vs frequency is akin to a bell shaped
curve with the maximum impedance at resonance.

208. Coax choke balun

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-09 05:58:16 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <envatoqmr1@news.hawaii.edu>
Source record: 47122

(I posted the msg below last week but never saw it appear.)

I plan on erecting a multi-band inverted V with several insulators and
associated shorting jumpers along each leg so that with all jumpers open,
the antenna is resonant on 10m; with the first insulator on each leg
shorted, the antenna is resonant on 15m; with the first and second insulators
on each leg shorted the antenna is resonant on 20m; et cetera. Shorting and
opening with the jumpers across the insulators is easier than winding accurate
traps (as in the trap dipole thread).

For a balun, I'm considering N4UJW's "Ugly Balun"
(see http://www.hamuniverse.com/balun.html).
UJW leaves the diameter of the coil form to the reader, only specifying that
18-21 feet of coax be used. Can anyone tell me if there is an optimum
diameter, considering that most of my operations will be on 20m and 40m?
(On that page, UJW has two balun projects -- see the first one.)

Hi Nate,

Simply examine the transfer characteristics of any series or parallel,
resonant circuit. It has a peak, not a band-reject characteristic,
that is why it is called resonant. You resonate traps at one distinct
frequency where the roll-off may serve the purpose over a slightly
wider region. A 10M trap does not "remove" the surplus wire for all
frequencies above, say, 28.4 MHz, and probably doesn't work for the FM
portion of the band.

True, but is there some other piece of Statute Law that states that legislation cannot come into force until it has been promulgated in the Federal Register?

Cecil,

Rohn 15 is tapered at the top of the sections to fit inside of the bottom
... I don't recall the exact dimensions, but the top, tapered part should be
"concentric" with the bottom of the next section and fit inside.
(you may already know all of this and may be describing something different)

The two pieces I have are not concentric and each
tapered part slants toward the middle at about 3
degrees rather than pointing straight out. The
slant is enough to cause the pieces not to fit
together.

Sounds like a manufacturing defect - or they got tweaked somehow ...

Good luck - if you try to bend them to fit, you really should check for
cracks - including all of the bracing and connecting welds.

I am also very familiar with the Military's method of training. even the FAA
does the same thing. They are trying to train a group of people that just
walked in off the street and a test said they had an aptitude to learn
electronics. In reality they may have no previous knowledge at all. All of
this training must take place in a few months so shortcuts in explaining it
may be taken, math used is often limited to an 8th grade level. Believe me
military training manuals are not the gospel of electronics but they are a
very good place to start without a pre-engineering prerequisit.

I gave up trying to talk while driving, it only took one close call for me
to quit. After I set up camp I lay some radials out on the ground and set up
an 18 ft fibergalss whip. Vehicle has antennas for 10/11m and 2m.

While driving, I find it hard to talk on a cellphone
but easy to talk on a ham radio. There's something
about half-duplex, push-to-talk that makes it easier,
maybe that I don't have to talk and listen at the
same time.

Perhaps. Intensity, proximity, and radiated frequency are important in my experience.

I worked years in a shortwave broadcasting plant where about a megawatt was being continuously radiated around the clock. No one of the many employees ever showed any effect from the exposure.

One the other hand, my ham friend, W5OQJ, was a movie projectionist. He contracted a chest cold. In an attempt to "bake it out", he exposed his chest to the the ultra violet from the electric arc of the projector. Next morning, he was dead.

Best regards, Richard Harrison, KB5WZI

They did in the mid 70s. We have a newbie at work that just got out of the Navy and was showing me his training books, I will ask him.I always considered flow from + to - becasue it make dealing with solidstate easier even though I was taught - to +. Also I always remembered they said it flowed from - to + to answer their irrelavent questions.Last I heard an electic current was a flow of cuurent carriers tha tcould be electrons or holes flowing in opposite direction, to me it is mox nix.

Not sure if changing the length of this type of antenna will work or not. It should be done with some caution as changing the length may effect the operation on the other bands.Dont make changes you cant undo. If you are uing the antenna with out a spring adding it may solve yuor problem for 10M but make it unusable for all the other bands without removing the spring.

The good are are pretty cheap, mine was a Wineguard and it worked great.The
only other one I have tried that really gave an improvment in sensitivity
was made by Blonder Tongue. There are a lot of others that just provide gain
and can actually make reception worse.

I know someone who drank water, and he got stomach cancer.

The effects of high intensity radar have been studied in great depth for decades. As far as I know, no evidence has ever been found that they're able to cause cancer.

Yea, me too Roy. Bun unlike you I hot jumped Loran transmitting
towers. And for those not aware the transmitting power was one
mega-watt. On a damp day you sure could draw a heck of an arc when you
jumped off.

When I read many academic books on antenna theory, most of them appear to say that the radials reflect the radio wave emitted by the vertical. I do not think that I am reading the books out of context. The replies from two professors of antenna theory indicate that they believe that the radials reflect the radio wave and form a mirror image.

Looking at the vertical monopole with four radials, I suspect that Douglas Miron is correct in his book. He says that the radials radiate but have horizontal cancelling fields.

I would expect the radials to radiate because current is forced through them by the RF generator. The current splits between the radials, thus causing the fields to cancel in the horizontal direction. The fields probably have an effect in the vertical direction, causing a change in radiation pattern and affecting angle of radiation.

I am not sure whether the return current through the radials causes any form of mirror image. On a PCB track above a ground plane, the current returns through the ground plane via the path of least impedance which is often directly underneath the PCB track. The PCB track is the positive voltage side. The ground plane current is the 0V side. It is said that the current in the ground plane mirrors that flowing through the PCB track.

Epidemiological studies often provide "indisputable proof" to people looking for support for their "beliefs". For instance, if they don't want a mobile phone tower in their visual environment, then the results of such studies are elevated to "indisputable proof" to oppose such structures.

The illogical thing is that there is more opposition to taller towers, though they are safer from an EMR perspective (both in terms of the radiation from the tower, and the power radiated by mobiles to communicate with the tower). That indicates to me that EMR safety is not uppermost in their minds, and their concern is a misrepresentation.

Thing is, when you depend on epidemiological studies, while you can create a lot of FUD (fear, uncertainty and doubt), you can't really prove anything safe.

Elevated radials do radiate. However, assuming a symmetrical structure, the radiation is minimal (assuming there's another normally radiating conductor in the system) because the fields from the wires nearly cancel in all directions. At right angles to the plane of the radials and along the center line, the cancellation is complete and radiation zero -- again assuming a perfectly symmetrical structure. In a typical ground plane vertical system, the contribution to the total field from the radials is minimal, in any direction.

Anyone interested in the pattern could model a radial structure by itself, with a source in each radial wire at the common junction. In the absence of loss, the model would radiate the entire amount of power fed to it, so it wouldn't be representative of the amount of contribution to the total field which the radials provide in a conventional ground plane type antenna. But it would show you the shape of the field radiated from the radials. I did this out of curiosity for two radials -- the pattern is a volume of revolution of a cloverleaf 2D pattern.

The radiation from buried radials is much less yet due to the lossiness of the ground.

There's no point in my commenting further on the concept of a few radials as a "mirror".

Yes, and as it was pointed out to me, it can (and probably is usually true) that the effectivity can be conditional on the FR publication if this is stated in the body of the law, as it was. I continue to be amazed at our system of laws; legislators make laws without knowing when they will actually become effective. The actual effectivity dates are delegated to non-elected bureaucrats who publish a paper. I cannot imagine that some laws whose effectivity dates can mean the accumulation (or loss) of wealth for each day publication is delayed or speeded up could have not a corruptive effect on these nameless people.

A war could be declared but not be put into effect until 30 days after publication in the Federal Register.

You seem to be assuming that all progressive individuals were blocked from amateur radio due to the code requirement. That is simply not true. There are many progressive individuals who passed or could have passed the Morse test. Also, amateur radio is not zero-sum: A new non morse ham does not replace an old morse ham; he/she simply adds to the existing base of all hams in the service. True, your claim is supported by the fact that natural attrition will generally result in young hams replacing old hams; however, future hams, young and old, who are not tested for Morse, might very well have wanted to pass, and indeed passed the Morse test, had it been required; therefore, non-progressives who could have passed the test, and who would would have wanted to pass the test are not prevented from entering the service. Also, the small subset of individuals who 1) could not pass the test and 2) are progessive is only a small percentage of all hams, both progressive and non-progressive, who either have or do not have the ability to pass a Morse test. There are many hams on this group whom I would call progressive but all of whom have passed the Morse test; they may not have favored it but they themselves passed it.

So, tell me how is there a "possibility" that amateur radio will change significantly when the impact of no code testing is obviously so small?

> Federal Register?

No - but there doesn't have to be.

The basic problem is that some folks either didn't read or didn't
understand
the test of the Report and Order.

FCC 06-178

can be downloaded from:

http://hraunfoss.fcc.gov/edocs_public/attachmatch/FCC-06-178A1.pdf

in PDF

On Sheet 17 (of 41) it says:

"VI. ORDERING CLAUSES

....

40. IT IS FURTHER ORDERED that Part 97 of the Commission's Rules IS
AMENDED as specified in Appendix A, effective [30 days after
publication in the
Federal Register]."

There's no need of any external law tying FCC action to the Federal
Register, because
the FCC did that as part of the R&O itself, rather than specifying an
effective date.

AFAIK, it's done this way to avoid conflicts. The R&O is effectively
"out there" for anyone to
look at, but if there were some sort of conflict with another govt.
agency, etc., or a mistake in the R&O, FCC could take action before
the effective date, and/or hold up implementation by not
publishing. That's extremely doubtful in this case - the delay in

getting the R&O published
is almost certainly simple bureaucratic procedure.

Not all FCC actions go through that procedure. Emergency declarations
are one example - they're usually effective immediately.

Sooner or later all the wheels will turn!

Honestly, Richard, your explanation was always my assumption and understanding. W8JI seems to be saying that by resonating them lower the benefit was lower loss. Now, I believe he was examining the 40m traps used in W8NX's antenna featured in various issues of QST.

I think I ought to construct the durned thing and not worry about the minutia. ;-)

Right. That has always been my understanding. I think W8JI was strictly looking at loss. His page has little commentary as I understand that what is there were slides at a Dayton forum.

A trap would naturally have higher losses at
its resonant frequency because that's where the
internal circulating currents are the highest.
Detuning the trap would reduce trap losses.
Removing the trap would reduce trap losses. :-)

So, my question is about choke baluns too. I just put up a shiny new GAP Eagle (yah, yah, I know short multiband verticals are snake oil, if I had a big lot I might do something different.) They recommended a small coax coil balun, but when I did that (as compared to just checking the resonance at the little tail coming out of the antenna) the 20M resonance went to pieces-- previously it had been <1:2 SWR (compared to 50 ohms) throughout the band, it went to >1:3 (but pretty flat) everywhere. I ended up just using a ferrite-bead choke balun I had around, and everything was fine. So, does anybody here have any idea why the coax coil choke and the ferrite bead choke would have been so different?

Rich, K6RFM

Hi Rich,

I have been using a GAP Eagle for years, and it resonates in every band as advertised (which is not to be mistaken for works miracles in every band).

It comes with its own ferrite choke (aka 1:1 BalUn) on the pigtail lead coming out of the bottom. Over the years and with wind, that has chipped and broken, but replacing it returned the original performance. By the way, I did have it elevated 10 feet up - this makes a difference.

We now have a USA Congress that was elected on an anti-Iraq war platform. Yesterday the key Democrats made the evening news in stating that they won't vote to cut off $$$ for the war. But, they will provide a non-binding resolution that the 'Sense of Congress' disapproves of the war. Heck, we knew that before the fools got sworn in!

If you're against the war, vote against paying for the war!! [become responsible ... not a wishy washy dish-rag!] AKA Put up or shut up!

Was the coax choke single layer or bunched?
How many turns on what diameter? Here's some
measured data:

http://www.k1ttt.net/technote/airbalun.html

Note the narrow bandwidth of the coax coils
Vs the broad bandwidth of the beads.

Hello Elden,

Take a look at Par Electronics 2m loops as a commercial option. Very good, sturdy antennas and horizontal orientation. I've used them mobile as a rover in VHF contests.

Another possibility is building a 2m Yagi. Look up "Cheap Yagis" on your search engine and find WA5VJB's article from the Clear Lake Amateur Radio Club. I've built the 432 beam and it works very well. The 2m version should also work.

Good luck,

Bill, W4WNT

Anybody ever mount a rotor in the attic and run the mast straight up thru the roof? Seems like I remember an article in 73 Amateur Radio or QST about this. I'm considering trying this, theirs a nice pop-out in my roof for a vent that would be perfect for this. Then the hole would not be in the main roof, just the small section of the pop-out. Seems like it would be fairly easy to seal, and could also put a large pan with a drain line under the rotor just in case any water did get thru. Any idea's, suggestions? Thanks

TimBob,

This is a great idea: with the shaft coming down through the roof into the attic, you can utilize the Armstrong[tm} brand of rotors and save a bundle! Armstrong[tm] rotors are both quicker and more accurate than other models, since they have none of the servo-feedback delays associated with traditional units.

You _will_ need to add copper or lead "flashing" to the mast, constructed so that it overhangs the opening and prevents wind-driven rain from leaching into the house. A drip pan is always a good idea, but it's _not_ a substitute for proper flashing. Check the roof timbers to make sure they're capable of withstanding the wind and/or ice loads the antenna may place on them; if in doubt, get a professional engineer to look it over.

G4FGQ, Reg Edwards, made lots of DOS programs. One was SELFRES3. Go for it at http://www.btinternet.com/~g4fgq.regp/ by clicking on "DOWNLOAD PROGRAMS FROM HERE". Then look for SELFRES3 (Performance of solenoid-wound choke coils, particularly coaxial chokes in antenna feedlines).

I'll bet it will make Reg happy if it is of use to you.

From: Yuri Blanarovich <K3BU@optonline.net>
Message-ID: <T4fph.463$sH1.309@newsfe12.lga>
Source record: 46979

I have question about performance of radial(s) in particular situation,
close or on the ground, but don't have NEC4 to model it.

Could anyone model with NEC4 engine these two situations please:

1. 200 ft tall vertical radiator, at 1.8 MHz with single horizontal 200 ft
radial,
a, at 6 ft above ground
b, 1 ft above ground
c, 3 inches above ground
d, buried, say 3 inches
using average real ground

2. Same as above cases but over "perfect" ground (salt water or salty marsh)

I would like to see the current distribution along the wires in all cases
and vertical radiation diagrams.

If you could email me the results or if you like to post them on web site, I
would appreciate that very much.

Thanks, 73 Yuri, K3BU

All except case d can be modeled with NEC-2 based programs including
EZNEC. NEC-4 won't give significantly different results.

I picked up an original 2m "BIG WHEEL" over the weekend - this will get mounted with my pair of original "SATURN SIX HALO'S stacked 6ft apart horizontally".

I plan taking the wheel apart - changing the rusted hardware and cleaning up the aluminum rods and other pieces - replacing both of the mounting U-bolts - I will measure the element lengths and take some pictures -

Please - email me off line for copies of the photos if you need them.

Just 4 turns about 6" diameter, bunched up and secured with cable ties as GAP recommended. Hard to believe there was some kind of narrow-band resonance that just hit 20M, but I guess stranger things have happened.

Sure, any small antenna like this is going to be a compromise. I was actually pleasantly surprised by the performance on 40M during the RTTY Roundup last weekend, I expected the Eagle to pretty much suck wind compared to my old full-size dipole, but it compared very favorably.

>

> performance.

I've got the GAP-supplied ferrite choke protected with heatshrink tubing, and the whole thing secured pretty well to the mast, so I'm hoping not much will flop around and it will last a good long time.

By the way, I did have it elevated 10 feet up - this
> makes a difference.

I've got it at the same spot as my old Cushcraft R5, a 10-foot mast on the porch roof secured to the main roof rafters so the mast sticks up about 3 feet over the main roof, the base of the Eagle ending up about 30 feet in the air. This basically is the only spot I have which is both reasonably accessible in case I need to fiddle with the connections and a good distance (at least 20 feet) away from major metal like power/phone lines, etc. It's also just about the midpoint of my lot so I keep the radiation as far away from my neighbors as possible;I figure that has to help with RFI and also helps me do the radiation-exposure self-evaluation with a clearer conscience.

I remember reading that article and it seems a ton of work/prevention goes
into that method. I'm going the Roof Tower direction and Glen Martin makes
some pretty nice ones, 4, 8 or 9 feet would seem to work better than what
you need to put a mast through the roof.

Just a 2nd idea

I'm going 9ft myself. Its all built but setting in my garage waiting for the
water we are getting in the Puget Sound to stop. Which at this rate might
be spring :).

**Thanks for your feedback! One of the reasons I am thinking about
thru the roof is for a little stealth, I would only want to put the
antenna's, (2 meter and 6 meters beams) about 5 ft above the roof.
They would be mostly hidden when looking at the front of the house from
the street. They are fairly small antenna's, I have them mounted on a
small telescoping mast right now with no problems for the last two
years. Rafters and joists are 2x6 and 2x8's, so I'm sure those are
heavy enough. I would think that between a cone shaped metal flashing
on the mast with rubber or some sort of UV resistant tape to seal it,
and then a rubber vent pipe seal at the roof level and maybe even some
o-rings on the mast inside the roof, plus a pan underneath the rotor
should insure no moisture inside. Of course all this would be grounded
very well! But a roof mount tower would sure be alot easier!

I guess it depends on which one you buy, but are you sure you want a clanging rotator in the attic? Might be loud.

291. Better for DX: Vertical or dipole?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-12 05:33:10 UTC
From: Rick <reply.in.newsgroup@spam.no>
Message-ID: <nv6eq298f2f5kdnekbmir1170an90ubc0j@4ax.com>
Source record: 47005

I am interested in operation primarily on 160, 80, and 40.

I have space for a full-size dipole for 160 but I cannot get it up very high, maybe 30 feet, higher than that only at great expense and with great difficulty.

I will likely put up a 160-meter dipole at 30 feet and feed it with ladder line and a tuner, and use it for NVIS work on 160-40.

For DX, though, I'm wondering if I will be happy with a vertical such as the Voyager DX from Gap Antennas, or if I should bite the bullet and go to the expense and difficulty of getting the dipole up 60-80 feet (which still won't be very high, compared with a wavelength, at 160 or 80).

What's your advice?

292. Re: Better for DX: Vertical or dipole?

Source record: 47006

> What's your advice?

Get a copy of ON4UN's low band DXing.

Search the Topband archives Re: antennas.

Measure/estimate your ground conductivity and permittivity and get
comfortable with a modeling program.

And finally, experiment.

I don't mean to be glib but there's really no quick answer to what
antenna you'd be happy with for DX on 40,80 and 160. 30 feet for a
horizontal antenna *is* too low, generally.

Maybe someone can comment on the Voyager DX... I can't, specifically.
Verticals are good, short verticals are compromises and must be treated
with care.

- - - - - - - - -

This is what I use:

http://www.n3ox.net/projects/sixtyvert

I can certainly work more 40&80m DX on this than on the 30 foot high,
100 foot long centerfed wire I used to use on those bands. As far as
160m goes, this is the first time I can work 160 DX at all...

73,
Dan

>What's your advice?

Hi Rick,

Choose your poison.

A 30 foot high 160M dipole is a notable ground hugging air cooled
resistor. A GAP is probably worse.

A combination of the two might be in order (which does NOT mean buy a
GAP to do this). Erect a 30 foot vertical and top load it with what
would have been the dipole.

I will leave to others what could be done in higher bands (with one
word of advice, GAPs don't usually perform very well on their lowest
band(s), but have been to be reported as good verticals otherwise).

Hmm... very interesting... and do-able. I've been thinking myself about erecting a vertical for 80/40 (but didn't want to waste my time). Thanks Dan!

It's more of a rumbling... but it comes through the bedroom ceiling,
which is not good.

For VHF yagis like the ones Tim is proposing, I had very good results
with a fixed pole and the rotor on top. A non-rotating pole is much
easier to install and make waterproof, and you can buy a ready-made
flashing adapter to take the pipe through the roof. (Back in the 1970s
I had to buy an extra concrete roof tile and drill a hole through it,
and then solder up a little 'stovepipe' flashing adapter from sheet
lead, but even that wasn't so hard.)

Inside the roof, I screwed a triangle of heavy plywood onto the roof
timbers to spread the sideways load, and then drilled the ply for
U-bolts. The pole should be supported as high up as possible, but don't
drill through any structural timbers. At the bottom of the pole, the
weight and sideways load were similarly spread over 3-4 ceiling rafters.
Very little noise comes down through the ceiling when the rotor is
outside.

It worked so well that I became more ambitious and converted the pole
into a guyed tilt-over arrangement, taking the antennas up to 10-15ft
above the roof line, and also making them easier to work on when tilted
over.

When we moved house, the pole was pulled out, and the original roof tile
was put back leaving no evidence.

YRMV (your roof, that is) but this option is well worth considering for
VHF beams.

Hi Rick,

As someone has said get a copy of ON4UN's Low band dxing..
I would not particularly recommend the Gap Antenna for Low Bands.

Than being said if you and put out a decent radial system for dx
Transmitting anyway I'd say you want some sort of vertical.

Why not try a Inverted L. Try to get as much vertical as possible.
Base tune it with a matching network- The SGC line works well for that
application. you can read more about Inverted L's in Cebik's write up at:

http://www.cebik.com/wire/ltv.html

Good Luck

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <12qeu7dilpqtve0@corp.supernews.com>
Source record: 47012

The short answer is that it would be very good at VHF and above, and poorer at lower frequencies. How it would compare with a metal mesh depends on the frequency, the nature of the mesh, and the application, so there's no simple answer to the comparison question.

To make it reasonably opaque to currents and fields, it needs to be at least several skin depths thick. As far as I've been able to tell, aluminum foil is roughly 0.02 mm thick. That would be 3 skin depths at about 150 MHz; below that frequency, it would be increasingly transparent. Above that frequency, it would have the same resistance as a group of separated wires having the same surface area. Because it has such a large surface area, I'd expect it to do as well as or better than most wire meshes down into the HF range. But as I said earlier, it depends.

There is an "external law" which ties all federal agency rulemakings to the
Federal Register.

It's called the Administrative Procedures Act and it's Title 5 USC, Chapter
5, sections 511-599.

The Administrative Procedure Act (APA) is the law under which some 55 U.S.
government federal regulatory agencies like the FDA and EPA (and FCC)
create the rules and regulations necessary to implement and enforce major
legislative acts such as the Food Drug and Cosmetic Act, Clean Air Act or
Occupational Health and Safety Act (and the Communications Act, as
ammended).

I'm sure that the delay (not abnormal at all) in publishing in the FR is
just that - the bureaucracy.

> Not all FCC actions go through that procedure. Emergency declarations
> are one example - they're usually effective immediately.

True - but the APA requires that there be very good reasons for not giving
the citizenry due and reasonable notice before new regulations take effect.

> Sooner or later all the wheels will turn!

Agreed ...

Good morning, Richard.

Actually, 30 feet is on the low side of "about right" on 160 and on
the high side of "about right" on 80, for NVIS work, of which I do a
lot. For DX, I agree that it's not of much use.

And yet...

My current antenna is an inverted V up about 35 feet in the center, 90
feet each leg, fed with ladder line. It started life as a
60-foot-high inverted V, full length for 160, in which configuration
it worked rather well. Then a storm came by and knocked a tree down
... well, I digress... :-(

I had earlier put up the inverted V via one of those "expensive and
difficult" mechanisms I mentioned earlier (hired a 60-foot cherry
picker and operator). I couldn't do that again, so I hoisted what was
left of the antenna up to the top of my 35-foot tower, and trimmed the
legs so that they would stay within the property line. Kept the
ladder line feeder, and I tune it with an LDG RT-11 autotuner with the
LDG balun.

I use that antenna on all bands including 160, with a Yaesu FT-817
running a cloud-burning 5 watts, and it works amazingly well for the
power level.

But, as usual, I want more. :-)

Thanks to you and others here for the feedback on the GAP. I REALLY
wasn't up for spending almost half a grand for a vertical.

Doesn't the horizontal part of the inverted L need to be as high as possible for best results? I'd run into the same problems I'm running into in putting a dipole or inverted V up high enough.

>Also check the
>vertical Vs horizontal noise level at your QTH.
>My 40m vertical had 2 S-units higher noise than
>my 80m dipole rendering it useless for weak
>signal DX.

I have a fairly high noise level around here on any of the horizontal antennas I've tried.

But, I have an MFJ-1026 "Deluxe Noise Canceling Signal Enhancer" :-) that does an amazing job of cutting down the noise IF the noise is primarily from one general direction (which seems to be the case around here although I haven't been able to pinpoint it).

That's one of the reasons I wanted to try some kind of a vertical and see how that worked.

I read somewhere that ground mounted verticals with radials on or buried in the ground tend to be noisier. Is that true? That's one of the reasons I was considering the GAP Voyager DX... doesn't require an extensive radial system.

Well, Florida had Punce de Leon, and "show-na-to-va" is a tennis
player, but he's too stupid to put two together in his own hand, so
can you blame him for having to find friends on cognet?

Perhaps he'll find Tommy, who doesn't know what the Fountain of Youth
is, either.

There was an old Bishop whose clucking
Confessed he knew nothing of fucking;
Forget a good boff,
He can't even fuck off,
So he just has to settle for sucking.

Rick wrote:
> Doesn't the horizontal part of the inverted L need to be as high as
> possible for best results? I'd run into the same problems I'm running
> into in putting a dipole or inverted V up high enough.

Not exactly. Make the vertical section of the Inv-L
as long as feasible. The vertical section is the
highest current section and therefore has the greatest
effect. Or instead of an Inv-L, make it a T antenna
with a vertical section and a symmetrical top hat.
The symmetrical top hat doesn't do much radiating.

Here's what EZNEC says using VERT1.ez as the reference.
40m 33' Vert1 has -0.04 dBi gain omnidirectional.

16.5'-16.5'Inv-L has 1.04 dBi gain with some directivity.

16.5'-23.5' T antenna has 0.19 dBi gain omnidirectional.
Note: 16.5' = vertical, 23.5' = horizontal top hat.

Performance wise, I don't think you could tell the real
vertical from the T except for the T's lower feedpoint
impedance.

>
> What's your advice?

High Rick,

Easy question, difficult answer.

Basically, a vertical antenna has more low elevation radiation with respect to dipoles at h<0.25*lambda above ground. However, it is, in most cases, difficult to get a reasonable efficiency in the vertical case. In addition, the amount of low angle radiation depends on the type of soil. Many horizontal dipoles operate better than verticals (on DX).

My practical proof is: when I get more signal strength (not S/N ratio) out of an antenna when receiving a station, I will generate more signal strength at the station's receiver. When you are able to do a simulation, simulate your antenna (with perfect ground) and determine the BW. Build your antenna and measure the bandwidth. When your bandwidth has doubled (with respect to simulation), your efficiency is about 50%. Make sure that your wire thickness in the simulation is equal to the real antenna.

Regarding horizontal dipoles. Up to h= 0.2*lambda, the radiation pattern does virtually not change; however the efficiency does. A halve wave dipole at h=0.1*lambda will put more energy in the earth (and radiates less) with respect to the same dipole at 0.2*lambda. At low height, an efficiency of less then 15% is not uncommon. It is because of the low efficiency (power dissipation in the soil) that most HF dipoles has reasonable bandwidth....

Above h=0.25*lambda the vertical radiation will reduce gradually in favour of the radiation at lower elevation.

When you are above bad soil, I would recommend you to try to increase the height (especially for 160m) of your dipole. This is because of a vertical antenna in combination with poor soil will probably have a low efficiency and radiation under low elevation will be suppressed (because of the relative high pseudo Brewster Angle).

When you can make h=80ft (24.3m), your 160m dipole will still have an "NVIS" radiation pattern, but with higher efficiency, so finally more radiated power in any direction (therefore also at low elevation). Same is valid for 80m, radiaton pattern will flatten a little bit in favour of lower elevation. At 40m, radiation at high elevation will become less, enhancing radiation at lower elevation. At 20m your will get multiple lobes in the elevation radiation pattern.

When you go vertical, your height will be limited too. Probably the height will be far below a quarter wavelength (for 80 and 160, unless you use a kite or balloon....). This will result in a low radiation resistance in combination with a high feed current. This feed current must be drawn out of a ground network. Mostly, the ground network will dissipate lots of the RF power. Of course, the situation is better when you live in an area with heavy, wet, mineral rich ground (like me).

Maybe for 40m you can get a (top loaded) vertical into a halve wave resonance. The input impedance will be very high (in the kOhm range), resulting in low feed current. This will reduce ground losses significantly. Another option to force the antenna into halve wave resonance is to add inductance in the middle of the wire. The disadvantage of relative short forced halve wave radiators is the very high end-fed impedance (>10 kOhm). Mostly this requires a dedicated tuner.

Top-loading the antenna (L, T, square, or multi wire cap) will give more current in the top of the antenna. This increases the radiation resistance (maximum factor 4) and decreases the losses in the ground system (better overall efficiency). It also eases matching.

Regarding the ground system. Try to get as much as metal connected to ground from where you feed the (vertical) radiator. More smaller ground rods do better then one very long one. Ground your (asymmetrical) tuner to the ground system and add a common mode coax choke between the tuner and Transceiver. There can be RF voltage on the tuner with respect to the transceiver's ground. If the VSWR of the radiator itself is not that bad, you may put the choke between the tuner and the radiator.

Another option is a floating ground (I am planning to do this for the next JOTA for 40m with a halve wave radiator). Two or three ground wires of 0.25*lambda are completely above the ground (some 6 feet). Depending on your back yard, this may be a problem. For a multi-band antenna this will require multiple wires.

A complete other option is using a (side-fed) loop.

The Voyager DX antenna.
I do not have experience with that antenna, however it is also used with a counterpoise kit (I saw on several reviews). If this kit is really necessary to operate the antenna, then it is a more or less asymmetrical antenna that needs ground. The bandwidth of 90 kHz at 160m is rather high. It may be the result of poor efficiency.

In brief:
#If you have very good ground, you may try a vertical monopole antenna.
#In case of very bad ground and no opportunity to make a good ground system, use the horizontal dipoles (as high as possible) and or use a vertical polarized radiator that has high radiation resistance at the feed point (halve wave characteristic prefered).

Best Regards,

Wim
PA3DJS

312. GPA vs Vert dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-12 18:00:46 UTC
From: Andr&#65533; <nospam@free.fr>
Message-ID: <45a7cccc$0$300$426a74cc@news.free.fr>
Source record: 46926

Hello,

(pse excuse my english)

I have some questions about GPA and vertical dipole
(vertical quarter wave with four horizontal radials and half wave center
feed vertical)

With a modelling software (MMANA) and antennas calculated in free space
conditions, at resonance,I get 72 Ohms for the dipole (correct), but only 22
Ohms for the GPA as I expected 36;

does anybody know the reason ?

Another question, The radiation patterns seem to be identical for both
antennas, so I expected the same gain with GPA or dipole, but the soft give
2.13 dBi for the dipole (correct) but only 1.57 dBi for the GPA.

Not due to the fact that the currents are greater in the GPA, as the soft
was working in 'no loss' conditions for the wires.

Tnx if you have solutions,

73

Andr&#65533;

I have a small rotator and a short mast fastened to a vent pipe in the back of the house for a UHF TV antenna. Something like that might work, if the antennas are not too big. I suspect the overall long term cost will be less.

Yes. I think the notion of putting the mast through a hole in the roof
dates to the time of "armstrong rotators" ie you'd rotate by hand, and
thus need the access to the mast.

You want some height above the roof so it doesn't affect the antenna, and
surely that amounts to enough for a small mast section and the rotor. Or
as you suggest, mount it on something outside that is below the roof, and
then have a mast to get it up high enough.

ONe winter, I had a two metre beam on a one section of mast, tied (I
can't remember with what) to the balcony (using the railing and a support
to the roof of the balcony) in the back. That was difficult to rotate by
hand, but it was doable.

When it went on the roof the next summer, again just enough mast was used
to raise it so the roof didn't interfere with the antenna's pattern, and
there was ample room to fit in a rotor.

I did not know that! Thanks Carl!

It makes perfect sense that there would be legislation requiring the
publication of routine new rules in the Federal Register before they
become effective.

> > AFAIK, it's done this way to avoid conflicts. The R&O is effectively

Agreed.

Also, after having made a couple of obvious typos and contradictions in
the "omnibus" R&O, FCC might be taking extra measures to be sure that
sort of thing isn't in this one.

Those emergency declarations are the exceptions that prove the rule
IMHO.

The T is better if he wants it to act like a DX vertical.
The L is ok, but if the horizontal wire is fairly long,
there will be a good bit of horizontal radiation.
This can be good for a mix of NVIS and DX, but
for DX only, the T is usually better. The T will have
an overhead null the same as a normal monopole.
I'd say most peoples L's on 160 have more horizontal
wire than vertical... :/ I know mine did. I could only
get mine about 45 ft vertical . That left 80-90 ft running
across the backyard. I often feed my coax fed dipoles
as a top hat vertical on 160 by shorting the coax, and
feeding as a vertical. At the moment I have a turnstile on
80m, and a dipole on 40. "6 legs total"
The 4 60 ft wires make a good "X" top hat..
MK

325. Re: Better for DX: Vertical or dipole?

Newsgroup: rec.radio.amateur.antenna

Source record: 46939

The T is simply a top loaded vertical. The top portion radiates an insignificantly small amount for the same reason ground plane radials don't radiate. (Hey, wonder if they act as an "image" mirror to reflect the signal into the ground?) (That was a joke.) The horizontal portion of an L antenna radiates like any end fed horizontal wire. If it's low, most of the radiation is at a high elevation angle.

A few interesting designs at this web site
[http://members.tripod.com/~KE4UYP/index-22.html] may help you.

One is a a linear loaded 1/2 wave inverted L fed at the top of the L
rather than the base.

Another is a top & bottomed hatted, bottom fed L.

Neither design requires radials.

Author includes theoretical radiation patterns & SWR curves.

You're right but I wasn't talking about the Inv-L above.
When I said "real vertical", I was talking about a
normal 1/4WL monopole. The T and the 1/4WL vertical
have about the same performance if the T's vertical
section is not too short.

Your sixtyvert antenna has me rethinking my vertical plans.

I have a forty foot utility pole laying on the ground while I plan the
details for a taller vertical.

In spite of my aversion to guys I think this pole is light enough to
be workable for me. My current vertical is a 45 foot wire off the
side of the tower tuned with an SGC-237. It seems to be working well
in spite of a minimal ground. It appears to me that the guy anchors
could be as simple as a few five gallon buckets of sand.

I sure hate to pay that much shipping though!

What if you have a lot of 50 to 80ft tall pine trees on the acreage? I live on a 500ft hill that slopes down agressively from a 2 acre flatter spot at the top. The hill is covered in trees. I have a 70ft tower on the highest knobe that I can load up well with a gama match on 40m, 80M and 160m. The wire ground plane I has 45x 120ft wires which run down the hill through the woods.

The Top-Band seems OK. On 160M I worked all states in one weeked last winter (contest). But on 80m and 40m I have had very little luck working anything. I suspect the trees are grabbing all the RF energy.

Because the trees are virticle conductors I'm thinking that a horozontal dipole might work better. I'll only be able to get it as high as the tree tops. Maybe an average of 55ft high near the edge of an east facing clift. Since I live on the West Coast this might give me good coverage on the States on 40 and 80 meters for next falls Salmon Run? What do you think?

For a long number of years I used a square loop antenna down low to the ground on HF. It was not fed in the 'usual' place, at the mid-point on the horizontal wire, either at the bottom of the square loop or on top. I chose to feed it half way up one of the vertical sides so as to obtain the best results I could from the vertical radiation for it. That so as to do the best job I could for 40 and 80 meter DX work without going after formal ground plane enhancement and working the feed point against that, as in ground plane verticals with radials.

In the 40 meter case the lowest horizontal wire was about ten feet or so above ground level. The actual loop was fed from a coax cable with the ground braid of the coax tied directly to the loop wire, and the feed match as a gamma match section using six inch open wire feed insulators for that, plus a series capacitor made from a cut off piece of coax cable the braid connected to the braid connect point end of the center wire of the feed coax and the inside coax wire connected to the gamma match line section. I had pair of three element quads made this way, with a pair of switched in or shorted wire stubs made from the same six inch open wire feed lines which if shorted, made that loop a director, and if opened, made it a reflector. They were supported at right angles to each other so I had four-way aiming capability here.

You can laugh all you want, but about 270 countries on 40CW confirmed from it wasn't too bad. And it placed way up there in the DX test single band entries for a long time from W5 land, which isn't really the easiest place from which to compete against the East and West coasts of the USA on low bands.

Yes, it was replaced by a four element phased vertical array, with elevated tuned radials. Which is definitely noisier on receive. But it has the advantage of being directionally switchable without going outside and getting on a step ladder four times just to change the fire direction in the middle of the night, or rain or .. even .. TRW's and twisters in this area of Texas. Of which there were only twenty tornadoes on the ground in a single day just a couple weeks ago right around here.

;)

For years now I've wanted to build a low three element rotary vertically fed 40 meter quad to test this against the four square switched phased vertical array I've used to romp the confirmed 40CW only card count to 321 now. That with about a level 5 or 6 ground level quality here in sandy pine tree country. But age, funds, want-to and other more important computer programming work in my preference list have gotten in the way.

If I ever can get this done I'd dearly love to post the comparative figures on a real-time real=workem romp! If it wouldn't be too much trouble for someone interested in this, making a 40 meter wire loop is pretty easy. You only need a pair of poles to support the top wire. I think you will be pleasantly surprised how quiet it is and how effective it is, if vertically fed, for working low band DX stations....

The closer to a 1/4 wave for the combined vertical
plus top hat wire , the better. You can even improve
farther as far as current distribution if you make it
longer. IE: 3/8 wave total length. That will raise the
max current point up into the vertical section more
towards the top, rather than the bottom. Course,
if you do this, you will need a cap to tune out the
reactance. Like Roy says, the hat radiates little.
Even just two wires is a pretty clean vertical pattern with
little radiation from the hat unless the total length
is so long as to place the current max at the apex
or into the horizontal wires . So I wouldn't get too
carried away with the total length past a 1/4 wave
if I wanted a strictly vertical pattern. When I ran both
an L and a T, the L would often do better at close to
medium distances in the early PM. But the T was
usually better once it stretched out a bit. So most
of the time, I preferred the T. At that time, I also had a
Z dipole, which was better for NVIS than the L.
Now all I have is the "coax dipole" T. I did away with the
others.. The Z dipole was generally the worse of the
three as far as DX. Course, I don't work too much DX
on 160m. I can't hear most of them with my micky
mouse receiving antennas... :/ I've heard W8JI working
stuff that didn't exist here on my radio.. I've pretty
much faced the fact I won't be having a killer 160 setup
until I can get out in the boondocks.

I have dug out of my box an old 1:1 balun I wound several years ago, possibly to a design in to the ARRL Handbook or the Antenna Handbook neither of which I sill have. This was wound with the main winding bifilar on one half of the (BIG) core and the third 'magnetising' winding on the opposite side of the core.

I can find many balun designs using just the bifilar pair and some with a third winding trifilar with the first two but can't find reference to separating the third winding. Can anyone shed any light on why I might have done it this way. I'm sure it was recomended somewhere but my memory is fading.......

I'm just curious to know why it was done as on a quick test with antenna analyzer and 50 ohm carbon resistor as a load it seems to work well from below 3 to 30 MHz. An oscilloscope shows the output to be well balanced.

I would be far more concerned as to what its common mode impedance is.
From what you describe it sounds like a voltage balun and those
generally have a poor common (blocking) mode impedance.

I would guess that you are right Danny and this is a voltage balun. I dug it out as I have recently moved to a flat in the centre of town 100 yards from a large telephone exchange and surrounded by noise sources. My old trusty vertical is giving me so much noise here that I want to put up a balanced antenna in the hope that this will reduce the interference. To minimise this noise I need a well balanced system. I already have coax up to the roof and balanced line would be difficult to route so am planning to fit a balun either at the dipole centre or a few feet below with a short balanced feed. I dug this balun out as it looked like it would give good balance. I have another (current) balun which has a simpler bifilar winding. I'm not sure which will be best for my application. Incidentally I only run QRP so efficiency is a major factor. I also considered a folded dipole using 600 ohm line as that would be less prone to static noise but would then have to look at a 4:1 design.

I would have to run the wires down the face of the cliff to make one of
those. Using NEC I just don't know how to simulate the ground effects
when the land falls away at a 30->50 degree angle. At one place there
is a 60 ft shear verticle drop. My unterminated beverage off the cliff
headed East works well on receive but it is terrible on transmit.

Beverages aren't supposed to work for transmitting so don't be
discouraged by that. I would think that the ground falling away would
be an advantage. Maybe Roy would care to comment on this, but I'd
just model it using the slope on those wires as if you have a really
high support point on the apex of the vee. Keep in mind that if you
don't terminate the legs of the vee then it will be bi-directional, so
if you're in the San Juans and point that sucker toward Florida you
should do equally well into Asia. Gee, I wish I had your problem! ;)

A troll? Not according to him, he's not. The poor, deluded dyslexic is actually convinced that he is defending what he calls his "honor" against a plethora of unseen attackers. Mark is not unlike Roger Wiseman. Like Roger who sees Lloyd behind every tree and around each corner, Mark sees Steve Robesin in every shadow and behind every post. Mark is quite obviously obsessed with Mr. Robesin, just as Roger is with Lloyd Davies.
We've all watched when Robesin makes a handfull of posts every few weeks and Mark goes ballistic by replying to the posts hundreds of times and for weeks afterward.

Go ahead and complain, though it will do little good. In fact, this clown actually thinks that he is helping to clean up the newsgroups when quite the opposite is true.

Hi Dick,

Have you considered a simple "Ugly Balun" (http://tinyurl.com/uvnt3)? It is nothing more than the end of your feedline coiled up, at the antenna feedpoint. Another better approach is a stack of ferrite cores at the feedpoint. These are commecially available, though you can easily make your own. I found some good reading here: http://tinyurl.com/uzvkh.

A folded dipole will look like 300 ohms. A 4:1 balun will present 75 ohms to the feedline; you'd need a 6:1 ratio in order to see 50 ohms.
That aside, a multiwire dipole (such as a folded dipole) will exhibit greater bandwidth than a single-wire dipole. My experience says that (at 80m) you'll see ~ 100 KHz for each set of wires, whether they're in the form of fan dipole, cage dipole, or folded dipole. I prefer a cage dipole over

the other two:
1 - same number of supports as with a single-wire dipole or folded-dipole
2 - matches directly into low-Z coaxial cable
I use one (in inverted-vee form during Field Day
(http://tinyurl.com/ybbsba)... approximately 400 KHz bandwidth, and uses
easy-to-make spreaders.

The third winding converts a current balun into a voltage balun. If the antenna is completely symmetrical with respect to ground, the third winding carries no current and does nothing. If the antenna isn't symmetrical, the third winding forces an imbalance in current between the antenna halves. The difference current flows on the transmission line as a common mode current. So at best it does nothing, at worst it causes the very problem a balun is intended to prevent.

There's more about this at http://eznec.com/Amateur/Articles/Baluns.pdf.

NEC is of course limited to perfectly flat ground of infinite extent. If the ground slope is constant for a great distance, you can simulate it by tilting the antenna model the opposite direction then tilting the resulting pattern. But that's about all you can do. I still use Brian Beezley's TA program for analyzing the effects of non-flat ground, but it's long been unavailable and I don't know of any program since which does the same thing.

N6BV's HFTA program is supplied with all recent ARRL Antenna Books, and is updated and improved in each edition. For anyone who doesn't live on perfectly flat ground of infinite extent, HFTA can provide a lot of answers to the old question: "How good is my QTH?"

However, HTFA is limited to horizontal antennas, and I don't know of any program that does the same for verticals (it's a much more difficult problem).

Thanks for the link Roy. A very useful document. Have also printed a copy
to place in the local club archives.

351. GR-1606A Mantenance Questions

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-14 16:40:25 UTC
From: William Becks <wbecks@centurytel.net>
Message-ID: <NNudnZBltbk3wDfYnZ2dnUVZ_h-vnZ2d@centurytel.net>
Source record: 46965

Has anyone on this group had any experience in performing maintenance on a General Radio Type 1606A RF Bridge? The "Reactance" capacitor on my 1606A is a bit intermittent (noisy) when tuning the bridge after initial balance in order to make a measurement. The bridge is in nearly mint condition and probably suffers from lack of regular use more than anything. I am hesitant to jump in and apply standard electrical cleaning chemicals without obtaining some advice from those of you that have experience with this bridge and that may have had to clean a noisy variable cap in one of these units.

Any recommendations would be appreciated including any suggestions on where to send such an instrument repair and calibration service. Sorry for asking these questions here, but I know that more than a few of you either have a 1606A/B or may have had one at one time or another.

Thank you,

Bill

William G. Becks, WA8WG

Hi William,

You already defined the cure: Use it more.

For calibration, there is not much that can be done except to compare
to standards (you won't have them). This would have to be done at a
primary or secondary Metrology lab, an instrument repair shop might
claim the capability, but without certificates of traceability you
would be paying for a job they didn't do.

Ive found that a tiny drop of DeOxit at the spring where the shaft contacts
the frame on most capacitors does wonders. Dont get carried away with it all
you need is just a little bit and dont get it on the plates.

363. do I have my antenna fundamentals right?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-15 02:37:35 UTC
From: Nelson Blaha <nelson.blaha@gmail.com>
Message-ID: <1168828655.591173.73110@51g2000cwl.googlegroups.com>
Source record: 46877

Having gotten some help around here on how to power my 2m mobile
indoors cheaply, I need to figure out a way to get an antenna. There
are probably a million holes in this plan, please point them
all out to me!

I intend to get a piece of square sheet metal (ground plane?) about
half a meter each way, and build a bracket to hold it outside my window
horizontally. In the center of the sheet metal I'll install an NMO
mount for my mobile antenna. I'm actually planning to ground the sheet
metal using the electrical ground in the wall socket (surely
something's wrong with THAT!) I look forward to better alternatives!

Hi Nelson,

Sounds like a lot of work when two, three, or four radials would do
just as well. The sheet metal plan is usually reserved for folks who
believe in the magic of magnetic mounts.

>I'm actually planning to ground the sheet
>metal using the electrical ground in the wall socket (surely
>something's wrong with THAT!)

Why bother? Electrical ground, and RF ground, and a Ground plane each
have different requirments. An electrical ground is not always a
suitable RF ground (and much could be said with all the combinations
and permutations of these three terms).

>I look forward to better alternatives!

Do less, enjoy more.

I believe that MMANA is a MININEC-based program. If that's correct, then there will be an error wherever wires connect at an angle, as they do in the ground plane antenna. The error can be minimized by making the segments of both wires very short near the connection point, either by greatly increasing the number of segments or by "tapering" the segment length. A capability to do the "tapering" automatically might be built into MMANA -- it was a feature of MININEC-based ELNEC 15 years ago. I don't know if that's the reason for your results, but that's where I'd start looking.

hi Nelson,

yes, it is a lot of work, you could just attach the magmount
to any metal object, patio table, metal railing or window a/c unit, etc.

or for a few dollars and less work build a great 2m antenna
using #12 thhn wire and a few feet of pvc pipe.

this is the half square, works great, it is directional.

http://cebik.com/vhf/hs.html

then you can try this one, the Moxon for 2m, little harder to make
but has similar gain to a 2 element yagi in less space and direct fed
with 50 ohm coax (like the half square is fed).

I've used my 1606, both A and B for many years, the A since 1968. I've found
that when the unit has been unused for several weeks, all the controls become a
little scratchy. But what works for me is just a little back-and-forth twisting
cleans whatever surfaces were dirty, and scratchiness disappears without needing
to apply any lubricant.

Way more metal than you need. I still have a cofee can lid with 4 1/4 lambda
raials soldered to it that I once used on a balcony. If you dnt already have
an antenna get one of those 1/2 lambda antennas that dont require a
groundplane.

372. What happens to a cage (fat) dipole with trap and extension

Newsgroup: rec.radio.amateur.antenna

I have been looking at the properties of a cage or fat dipole. This is efficient and has a wide bandwidth. But what happens if a trap is added to then with an extension to cover an additional lower band. Will the high Q trap significantly reduce the efectiveness of the cage dipole in efficiency and bandwidth? I was thinking in terms of a cage dipole-trap-cage extension. Any thoughts?

Thanks Jimmie, Markus, Richard for your advice. I'm working without tools... what I really need is a drill. For the moment I've put my mobile antenna out my window on a four-foot section of I-bar. It works pretty well for receiving, but I won't know how well it transmits with virtually no ground plane until I'm good and licensed. That coffee can bit gave me a good idea for an RF ground plane, though.

I have to confess, I expected a much kinder reaction from uk.amateur.radio, but some of them gave me some harsh words just because I wasn't licensed! It's good to know I can get friendly help somewhere.

Hi Dick,

It would seem to be a contradiction in sizes (the coil and cap have to
be much smaller), but then when I think of cage antennas, I see:
http://home.comcast.net/~kb7qhc/antennas/verticals/Cage/cage.htm

The point of the cage is to not need adornments.

Dont even think about transmitting before you get your ticket I know this can be a temptation once you have your equipment. The FCC is very serious about this. You can be very heavily fined and lose the chance to ever be a licensed ametuer radio operator. This is why I advise anyone who wants to be a ham to get their ticket before getting their TX equipment. THE TEMPTATION can be too great.

Since the elements of a cage dipole usually come to a point at both ends (the feed and the far end for attachment of a support) I can see no problem in physically adding a trap.

Above the trap cut-off frequency the extensions will have little effect on the performance. At lower frequencies where you will effectively have a dipole element with a fat portion and then a thinner bit at the end , it should work ok but you may need some modelling to see exactly what happens to the bandwidth.

I have modelled it in MMANA (my cage is similar to 'fat dipole2.maa') and it
looks feasible. The cage resonant frequency drops a tad but the extension
after the trap, modelled with a 3mm wire, does resonant nicely. This allows
me to add an extra band somewhat below the normal low limit of the cage
dipole. My modelling still shows a reasonable bandwidth for the main cage
dipole but I suspect the trap will have some complex effects above and below
resonance. I will have to try it to see how much it affects it will have.
It will be easy to clip a trap to each end of the main dipole for the tests.

hi nelson,

You've got to start somewhere, and listening in on qso
is one of the best ways to learn.

Not sure where you are, check to see if there are any
nets on the repeaters in the area, our club has tech net
weekly, great way to learn about what others are doing
(right or wrong ?) !

Try a search for other hams in your area using qrz or other search tool.

have you visited www.eham.net ?

Thanks for the advice Jimmie, it is indeed a strong temptation but I've resisted it so far.

Bud, I'm on that! I've got two pages of repeater frequencies for all over the Dallas/Ft Worth area (I'm conveniently in Arlington right between) and I've been listening off and on for weeks. I feel like as soon as I get my call sign, I could hop right in! That is, if my antenna transmits as well as it receives... no ground plane, as I've explained. Do you think the bottom of a peanut can would be enough?

Weirdly, I'm waiting on getting my call sign before I register on eham.net, since I'm gonna use my call as my username. I'm sort of a google fan anyway, I get to usenet through google groups-beta and that's good for me.

QRZ search tool is news to me, I'll try that out.

Antennas are small on 2m.. He could live a little and use 3 elements
and have a good bit more gain. But then he has to rotate the thing..
I recommend a easy 1/4 wave ground plane to start. It will work about
as well or better as any of the other "easy" vertical whips for 2
meters.
Attaching a 2 meter whip to a railing, table, AC unit , etc is going to
function in a fairly poor manner. The ground radials need to be
resonant to function properly. Would be much better to use 4 simple
quarter wave radials. You can slope them down at about 45 degrees
to get a better match, and maybe a tiny bit more gain.

```
OK Cecil, thank you for the test.
```

The question now, is, why a GPA in free space does not present a 36 Ohms
imp&#65533;dance ?

```
I use a full sized GPA on 40m, 6 meter high and a quasi 1/1 SWR with 50 Ohms
coax line;
with 36 Ohms in free space I had 14 Ohms for losses in the ground and 36
Ohms for my correspondant;
but now, it is 28 Ohms for the ground and 22 for the QSO...
```

```
To night, I can not open your page www.qsl.net/w5dxp/dipvsver.htm
```

```
I was interested to see if you get the same results,
I use also a half wave dipole 16m high and the GPA, with a slight advantage
for the GPA during the night and distant stations, and the opposite during
the day time and short distances;
the ground is very poor here.
```

If the theory is correct, exotic matter occupies space in such a way that sometimes enough of it gathers through gravitation attraction to create "mass" and form a particle that suddenly appears and then quickly disintegrates after perhaps a nanosecond of existence. Effectively, particles pop in and out of existence in space.

To describe what exotic matter "is" during the majority of its time when it does not exist as particular mass depends on what the definition of "is" is. (Hmmm, I heard that quotation somewhere ;-))

Someone else posted that.. Myself, I wouldn't use one of those on 2m.
Sure, it would work, but for about the same or less amount of work
you could have a small 3 el yagi.
I would not use a directional antenna unless you had an easy way to
turn it.
A ground plane is super cheap, and will do just fine. You can place
them
on a mast, hang them from ceilings, etc. I've got a ground plane hung
in my
attic for emergency use. With 2m FM, gain is not really that important.
Decoupling from the feedline is though. The decoupling with the GP will
be fairly decent. If you use an off size "counterpoise" to mount a whip
on,
it's not resonant, and generally will do a poor job vs a complete
antenna.
You will find in most cases like that, the decoupling from the feedline
will be
poor too.
I'd start with a simple 1/4 wave ground plane, and go from there.
All you need is a SO-239 and 5 pieces of wire about 19-20 inches long.
Most bend the lower ground radials down at about 45 degrees to
get a better match to 50 ohms. You can set one on a table unless
the coax is thick... :/
Can't get much cheaper than that, and it will work well. To me, the
half square is too much work, too little gain for 2m.. Good for HF
tho..
A 3 el yagi would clobber that thing on 2m, and isn't too much bigger..

Where does the 36 ohms come from? Is it for a quarter wave monopole
mounted on a perfect ground plane?

Is the radiation pattern of a quarter wave monopole mounted over 4
quarter wave radials the same as a quarter wave monopole mounted on a
perfect ground plane?

Though you might use the term GPA to refer to a quarter wave monopole
mounted over 4 quarter wave radials, it is not the same as a quarter wave
monopole mounted on a perfect ground plane.

IF I were working off a balcony I would use a Yagi or maybe a quad sense the
building will be blocking the signal in at one direction any way. I used to
hace a two element quad I made on a broom. I would sit on the balcony and
hold the quad in one hand and my HT in the other. BAd thing is that now
there is now way to hold the beer.

Hello.

Is there a way of using the Icom 910H (supporting just AFSK) for
receving and transmiting FSK modulated signals with the help of the
KAM-XL TNC?

The question is why is he modeling antenna in free space??
Planning to go there anytime soon???
Why would anyone model especially vertical antennas in free space (besides
trying to see how the donut looks)?
Verticals especially work with ground in forming the pattern and impedance.
I use and model my verticals on earth. JMO

With a vertical monopole antenna, the field emitted by the radials forms a near field and interacts with the wave radiated by the vertical element. Is it mainly in the vertical direction that the radial fields interact with the field from vertical element? I would expect the antenna feedpoint impedance to be formed from the length of antenna conductors and the interaction of the fields.

If a monopole is simulated in a NEC program above a perfect ground plane, is it possible to see the reflection? I would expect NEC program to show reflection of waves from metallic surfaces e.g reflection from perfect ground plane or parabolic dish. Can a NEC program allow the user to see whether the wave is reflected (as for perfect ground plane) or whether effect is due to wave interaction (as for radials)? Can the user then vary a finite size ground plane to see whether antenna impedance comes from reflection or wave interaction?

The fields "interact" wherever they exist.

> I would expect the antenna feedpoint impedance
> to be formed from the length of antenna conductors and the interaction of
> the fields.

You should also expect the feedpoint impedance to be formed by the
ratio of the voltage to the current at the feedpoint, among other things.

> If a monopole is simulated in a NEC program above a perfect ground plane, is

An interactive video game it's not. Perhaps if you were to become a
NEC user, you would come to know these things and more, first hand.

Isn't the whole question of whether it's a reflection as from a conducting plate, or radiation from the radials based on misunderstanding what a reflection is?

The reflection from a conducting plane is the sum effect of the radiation from the currents induced in the plane by the incident field, say from a quarter wave vertical. The reflection forms an image 'behind the mirror' of the source of the incident field, for example a quarter wave vertical 'under the plane'. If these currents are radial then the plane is well approximated by a large number of long radial wires. The high resistance at right angles to the radials doesn't matter because no current is flowing in that direction. The plane is not so well approximated by a small number, say 3 or 4, radials, especially if they are short, say a quarter wavelength.

However the approximation may be good enough to allow us to regard the short radials as reflecting the incident field from the quarter wave vertical especially if we just need a rough picture of the situation and a rough estimate of the input impedance.We may need to keep in mind that the reflection is due to radiation from the currents in the radials or we may be able to forget it. If we want the antenna pattern in detail and the input impedance accurately we have to do the maths properly. That's not simple even for a half-wave dipole!

Brian LA0DG

What do you mean when you say that waves interact with each other?
Explain what you mean by the word "reflection."

There is no contradiction in quantum electrodynamics.
A photon encounters an electron in a radial and is
absorbed. Later, that same electron emits a photon.
The original photon energy could have come from
anywhere. If it came from the vertical element in
the first place, it is a "reflection" but that is
irrelevant. If it came from that same radial in the
first place, it is not a "reflection" but that is also
irrelevant. If it bounced off a flagpole before it
was absorbed by the electron, it is a "reflection" but
no rational person cares. The photon cloud surrounding
a radial contains photons that came from that radial
and from everywhere else. That some photons must be
put in a basket labeled "reflected" and some put in
a basket labeled "not reflected" is simply nonsense.

The very concept of arguing whether a photon was
reflected or not seems to violate the uncertainty
principle. There is only a probability that it was
reflected.

supported hostilities against the United States' is in the eye of the
beholder, and this administration has proven itself to be astonishingly

impatient with criticism of any kind. The broad powers given to Bush by this legislation allow him to capture, indefinitely detain, and refuse a hearing to any American citizen who speaks out against Iraq or any other part of the so-called 'War on Terror.'

"If you write a letter to the editor attacking Bush, you could be deemed as purposefully and materially supporting hostilities against the United States. If you organize or join a public demonstration against Iraq, or against the administration, the same designation could befall you. One dark-comedy aspect of the legislation is that senators or House members who publicly disagree with Bush, criticize him, or organize investigations into his dealings could be placed under the same designation. In effect, Congress just gave Bush the power to lock them up." -- William Rivers Pitt

"It has become clear in recent months that a critical mass of the American people have seen through the lies of the Bush administration; with the president's polls at an historic low, growing resistance to the war Iraq, and the Democrats likely to take back the Congress in mid-term elections, the Bush administration is on the ropes. And so it is particularly worrying that President Bush has seen fit, at this juncture to, in effect, declare himself dictator." -- Frank Morales

"No man in History, including JESUS CHRIST, has directly revealed to the World the SATANIC WEAPON used to enslave mankind -- INTELLECTUAL THOUGHT!!" -- Ray Karczewski repeatedly proves his words in every post he makes

408. Reflection xfmr for two wire beverage?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-18 14:11:39 UTC
From: Kenneth Grimm <kgrimm@adelphia.net>
Message-ID: <ctuuq2tjqvfcqrpmj1bs4ni6ga1j1moaa9@4ax.com>
Source record: 46922

I have successfully installed traditional one wire beverages, both terminated and unterminated. I've managed to wind 9:1 transformers that work well using both normal toroids and binocular cores. However, I'm flummoxed when it comes to two-wire beverages using a reflection transformer. The two "head-end" transformers seem to be fairly straight forward and I suppose can be checked using my MFJ-259B for a good match. However, look as I might, I can't find anything specific on 1) how many turns, etc. for the reflection transformer and 2) how to measure it to make sure it is working properly. There is nothing helpful in either ON4UN's book or the ARRL Antenna Handbook. W8JI's web site includes just enough information to make me want to buy the units that he designed that are being sold for big money by DX Engineering. As usual, not having big money at hand, I prefer to home brew and have the 73-mix FairRite Products 2873000202 cores to hand and plenty of wire. What I need is some Elmering.

I would sincerely appreciate hearing from anyone who has practical experience with the two-wire reflection transformer equipped beverage antenna and can offer me any help with the transformer windings.

73,

Ken K4XL

Hi David,

No.

>I would expect the antenna feedpoint impedance
>to be formed from the length of antenna conductors and the interaction of
>the fields.

Sure. There is nothing you've offered to suggest otherwise.

>If a monopole is simulated in a NEC program above a perfect ground plane, is
>it possible to see the reflection?

Yes. Even above an imperfect ground. Plane has nothing to do with it
except for the matter of geometry - radials even less so.

>I would expect NEC program to show
>reflection of waves from metallic surfaces e.g reflection from perfect
>ground plane or parabolic dish.

You should then expect an NEC program to show that reflection in
relation to wavelength. They do this to as near to what is observed
as to show no difference, naturally.

>Can a NEC program allow the user to see
>whether the wave is reflected (as for perfect ground plane) or whether
>effect is due to wave interaction (as for radials)?

NEC is not responsible for insight or interpretation. That only comes
with experience.

>Can the user then vary a
>finite size ground plane to see whether antenna impedance comes from
>reflection or wave interaction?

The user might, but the proof of an argument is through a chain of
evidence.

A simple test of "reflection from radials" in a real implementation
(with ground):

1. Change the angle of the radials by 45ï¿½,
does the lobe angle change by 45ï¿½?
Explain why reflection does not follow convention.

2. As suggested by Roy, add a top hat with a structure that identical
to the radials,
does the lobe angle point into the ground?
Explain why reflection does not exist in this case.

3. Alternative: invert the radials/vertical, it is now upside down,
does the lobe angle invert with it?
Explain why radials are special only in the conventional case.

You might want to repeat these in real space, but then you have
removed the reflector, ground. Without it, what would you offer as a
proof of reflection that can be verified through any of the three
simple tests above?
Explain why those tests demonstrate reflection in free space when
those tests above do not.

On my "Things to do List" I plan to spend some time with EzNec and a
ground plane in free space.

What I hope to better understand is the effect of the the quality of
the ground plan in the are between a modeled "real ground" and a
modeled "perfect ground".

I don't know the free space model will be valid, but I hope to learn
from the exercise.

I could just ask another series of "dumb questions" here but I fear
some of those who are so generous will tire of my noise!

When I modeled the vertical with a perfect ground I was expecting half
a vertical dipole and that is not what I got!

Cecil Moore wrote:

> There is no contradiction in quantum electrodynamics.

There's certainly a paradox.

> A photon encounters an electron in a radial and is
> absorbed.

We know that electrons are inspired to move in a particular fashion
when they are irradiated. But how does a photon tell the electron
which way it should move? Kinematics would seem to have little to do
with this phenomenon.

> Later, that same electron emits a photon.

A photon which, if the direction in which it is emitted is unknown,
can be made to create a diffraction pattern - implying that a wave was
emitted rather than a particle. Putting us right back where we started.

> The photon cloud surrounding
> a radial contains photons that came from that radial
> and from everywhere else.

But what is it about this "cloud" that is actually cloud-like? Isn't
it really more like a wave of photons? :-)

> That some photons must be
> put in a basket labeled "reflected" and some put in
> a basket labeled "not reflected" is simply nonsense.

I think Feynman uses almost that exact analogy, with probabilities
assigned to each, in the first few pages of QED.

Energy and momentum must be conserved.

> A photon which, if the direction in which it is emitted is unknown, can

Allow me to paraphrase Feynman: Only particles exist.

> But what is it about this "cloud" that is actually cloud-like? Isn't it

If you prefer liquid analogies to gaseous analogies, feel
free.

> I think Feynman uses almost that exact analogy, with probabilities
> assigned to each, in the first few pages of QED.

You missed the point. That an individual photon must be
put in a basket labeled "reflected" and some other individual
photon must be put in a basket labeled "not reflected" is simply
nonsense. Talking about exactly where an individual photon
goes is nonsense.

I am a filthy c*nt named madMaxWhore. I am the type of girl that only gets taken to White Castles because guys give me a $2 or $3 dollor limit. If I want something more expensive, I have to go by the dumpster behind White Castles and open my legs for 5 cent deposit cans and then after I get sodomized and f8cked by the homeless population, I have to redeemed the bottles and cans to get the extra money. The homeless men love sticking the cans up my filthy vagina and watching them melt from the toxcitiy.

Sometimes the stores won't take my cans and bottle because of the thick discharge on them and the foul stench of the cans and bottle (because of my diseased discharge)

By the time I get back to the fast food joint my date is gone. I guess they met someone that will douche and won;t settle for a skanky whore like me.

I lose every flamewar I enter because the toxic fumes from my diseased undouched vagina impair my already damaged brain. I want to be owned by the best flamer I ever encountered in life refuses to own me because my vagina is so filthy and toxic. I get beat down by everyone on usenet. Even my provider Usenetserver.com beats me down.

I want to get married but I am a known whore whose only good for pumping and dumping. I am so embarrassed at being thoroughly thrashed by all of my Usenet enemies. For those that aren't so picky about douching, I am owned by 70% of the alt.usenet.kook population.

My daddy initiated me into the world of sex and I have been getting buttsexed by him regularly ever since I was five years old. I drip toxic discharge from my filthy vagina. I have vaginal hair longer than the hair on Crystal Gayle's head. Guys just pump me and then dump me. I'm the kind of girl that gets sexed in alley and behind dumpsters

it.discussioni.geometri,it.comp.giochi,rec.radio.amateur.antenna,hr.rec.glazba.snimanje,alt.consciousness.4th-way

Dirk was on the West Coast when he got the call. An old friend at the Toronto police department thought he would like to fly up and take a look at a homicide which had occurred the previous evening. He decided to skip the last day at the World Holistics conference and take the next plane out of San Francisco.

The flight was bad; Dirk had been hit on the back of the head by the Newspaper trolley, the drinks trolley, the dinner trolley and now the gift trolley. When the hostesses weren't trying to tear his arm off they pestered him to stop leaning into the aisle - ignoring the fact that the guy next to him was taking up one and a half seats. Air Canada used to be the flight which was so good you just didn't wanna get off - on this occasion Dirk would be glad to see the back of the plane and the over sized alternative comedian wedged into the window seat.

After breathing in a couple of lungfulls of crisp Canadian air Dirk took a taxi into town. There was a small group of demonstrators outside the MacDonalds and the taxi driver insisted on stopping on the opposite side of the street. "Don't Eat Meat" the placards read and the demonstrators chanted. A couple of policemen where stopping the crowd entering the restaurant itself - one held up his arm and challenged Dirk. A wave of the fax he had been sent and the policeman pushed open the door.

There were few customers in the restaurant. Not surprising really with a demonstration going on outside, half the dining area roped off with tape and a dead body seated at one of the tables. "Mr Gently sir" the officer in charge called out as he peeled one end of the tape off a column "We were told not to touch anything til" you got here".

The body of the man slumped awkwardly in a chair. Then even a dead body would start getting uncomfortable in a MacDonalds chair after twenty minutes - and this one had been there for at least eighteen hours. Two back legs and the tail of a cat hung out of the man's gaping mouth. Dirk turned to the officer, "I suppose you are going to tell me this is the darndest thing you ever saw?"

�Ain�t this the darnd...�. The officer seemed annoyed that Dirk had second guessed him. �We�re removing the body in a few minutes, so if you can get through as quick as possible�

�Many people eat cats in fast food restaurants?� Dirk asked and without waiting for an answer leant over the table to pick up an untouched burger. �And what�s this?� he asked waving it in front of the officers face.

�It�s a Vedgie Burger� The waitress, who was cleaning one of the adjacent tables, shouted across. She walked over to Dirk. �We started doing them because of that lot out there� she nodded towards the protesters who were pressing there faces against the windows �They�re called Linda McCartney Vedgie burgers - ever heard of them?�

Dirk suddenly felt faint, perhaps a combination of hunger and jet lag. �This is deja vu all over again� he thought to himself. He glanced at policemen - at the badge on his shoulder �OPD� but this wasn�t Ontario this was Toronto. OPD - Officially Pronounced Dead. It dawned on Dirk what was happening, he knew what he would see if he looked out of the window. Sure enough, there it was, the Volkswagen Beetle parked across the road - number plate 28IF - 28 IF Paul McCartney had lived. And amongst the lyrics of the song blaring out into the restaurant he could pick out the words �I buried Paul�. Now it was though Dirk was viewing the whole scene though a TV screen. This was conspiracy. Not -a- conspiracy, or -the- conspiracy, but just plain conspiracy.

�You look faint - are you OK mister? The waitress asked.

Dirk shook his head �Probably a bit hungry� Then to economise on dialogue took out a pack of cigarettes and held it out towards the girl. She was about to take one but Dirk snatched the pack away, held it up to his mouth and drew out two cigarettes. He lit both then passed one of them to the girl. It was the closest he had come to a sexual encounter in three months.

�Want a Burger?� the waitress asked.

Dirk looked down at the Vedgie Burger on the table. �No thanks - just a plate of fries�

The waitress walked away and Dirk looked around the room. Apart from a family seated in the far corner there was only one other person in the restaurant - and he wasn�t eating. The guy was about mid twenties and had straggling, shoulder length hair. On the table in front of him were lots of pieces of paper cut into squares. Every so often he would pick up a camcorder and pan it around the room and then, when he was finished, speak into a microphone which was attached to a

tape recorder. Dirk walked over to where the man was sitting.

The small pieces of paper had paragraphs of text written on them and were stuck to the top of table with blobs of mustard. Lines had been drawn, some solid some dotted, on the table top with a marker pen. The lines ran from one piece of paper to another.

“What are the lines for?” Dirk asked, realising straight away that “What the hell are you doing?” would be more appropriate.

“You see” The man replied nervously “The dotted lines are weak links and the solid lines are strong links. The dotted lines are things which are happening in the rest of the world and the solid lines are things which are happening to me. Now you see I draw over a dotted line, replacing it with a solid line, when I can link something back to me. Like this” The pen squeaked over the Formica and before Dirk could interrupt the man added. “You see I lost my short term memory and, as a consequence have a very short attention span. I write down, record and film everything then put it all together later”

“So” Dirk interrupted. “You filmed what happened here?”

“Yes, yes, it’s here on this tape” The man pushed the cassette across the table. On the label the words “Grassy Knoll” had been crossed through and replaced with “MacDonalds”.

Suddenly the man sprung from his seat. Dirk turned and saw that the body was being removed on a stretcher. As it passed the man picked a small object off the edge of the stretcher itself. “This is important” he said, laying a blood stained bullet on one of the small pieces of paper on the table.

Suddenly the room was filled with a deafening throbbing sound as a Black Helicopter landed in the street outside. Two men in United Nations uniforms got out and collected the stretcher. Back at the table the long haired man was replacing all the dotted lines with solid ones. Dirk panicked and began to walk backwards at some speed. Barging through the swing doors he stumbled into the kitchen, tripped and felt himself sink slowly into a large vat.

“The guys fallen into the batter” Dick heard someone shout before he sunk below the surface. He came to sitting in a chair with the batter solidifying all over his body. He surveyed the room through two eye-holes someone had cut. Suddenly the chair on which he was sitting was picked up carried through the restaurant and out of the building. As the chair was being lifted and put into the back of a van, Dirk caught a glimpse of the waitress following him. “Your fries mister, your

plate o...�.

The doors of the van shut and Dirk tried desperately to steady himself as it sped across town. Eventually the doors flew open and Dirk was flung into the road at which point the solidified batter shattered and set him free. Standing up he found himself outside the international departures terminal of Toronto airport.

In the departure lounge Dirk had time to reflect on the day�s events. He had got caught up in the conspiracy theories and the haphazard welding together of pieces of irrelevant information. It was time to catch the person who was operating the bizarre cognitive engine which appeared in front of him like a fairground mirror, distorting any flaw it could find in his own, fragile, map of the real world.

Dirk leant into the aisle of the plane as it took off for London. The oversized person next to him swung his arms violently as he complained about every thing from the supper in a plastic tray to the state of British politics. With a shaven head and a badly fitting suit the man looked as though he could have worked behind the reception desk of the Kremlin. However when he spoke he did so in a Liverpudlian accent. �Me I blame the Con-serv-a-tive government, me. The Tour-rees. That-cher. Me. They need a good kicking� He jerked his feet forward and struck the seat in front with his Doc Martins. �With these. Me Doc Martins. Doctor Martin�s, Doctor Martin�s, Doctor Martin�s Booots!� The phrase was now being sung over and over again as the man writhed in his seat and clicked his fingers.

Dirk looked down at the boots and thought of the reaction most people used to deal with the paranoids at the end of the wire. A nice quick kick. �Oi nutter - get some therapy�. This is the easy way out and perhaps the safest. After all there you are sat, alone, in front of the screen. No body language between you some paranoid. No way of telling if he really is some gibbering psycho. Look at it too long and you be drawn in. Fall into the tangled database of weird links with him. Who knows he may be watching you, reassembling and linking your experiences with his. How sure are you of you own cognitive threads. After all cognition is only a bug fix for a neurological system which was designed in a hurry - it�s abused by everyone from politicians to advertisers. If people really can convince each other that a bottle of washing up liquid is as exciting as an orgasm using just television God knows what they can do with a computer. Better to avoid the risk. A swift kick. After all if you�re Homophobic you put the boot in because you are scared of any ambiguity in your own sexuality

- why not be Nutterphobic as well.

```
Although Dirk would have liked to devoted time to tracking
the culprit down he decided to let it rest. The Internet
changed over the next twenty odd years. A lot of the people
who used it went out and got lives. And those who already
had lives burnt them away. The number of users had dwindled
after someone had invented a C++ program, with truth as a
variable, to deal handle politics and government. Dirk had
already retired from finding old ladies cats with the help of
obscure science when he got another call from Toronto.
```

It was 4th March 2025 when he booked onto the Air Canada flight from Heathrow. The silver haired woman in the seat next to him painted bright red lipstick around her mouth. ‘Of course it was no surprise to be offered the job after Claire Raynor retired’ she sneered’ After all I used to be a psychiatric nurse... Now if Blokes had periods they would understand...’

By chance the taxi ride to Toronto mental hospital took him past the MacDonalds - where the whole thing had started. Of course it was barely recognisable having become a Church Of Scientology Vedgie Bar. Police in riot gear kept the two sets of demonstrators apart. Dirk didn’t really know what to expect when he got to the hospital. The girl at the reception desk directed him to a row of chairs in a wide well lit corridor. There was a strong smell of disinfectant, the furniture and the carpets were immaculately clean and behind the rows of teak veneer doors the ‘nutters’ were all safely locked away. For some reason Dirk started thinking about CompuServe forums.

A tall blond woman in a white coat approached. ‘Mr Gentle, I assume’

‘Yes’ Dirk replied shaking her by the hand. ‘You’re the nurse who...’

‘Doctor’ She interrupted, ‘Doctor Killfile’ She led Dirk across the corridor towards one of the doors then stopped with her hand resting on the handle. ‘Now you know about this person don’t you?’ and after Dirk nodded she continued ‘Don’t tell him anything about yourself - don’t let him get into you head. If he does he’ll screw it up’

The door opened to reveal a frail man sitting in from of a TV screen. He had a keyboard on his lap and next to the television was a computer screen. Dirk glanced at the walls of the room and remembered that his settee at home need upholstering. The nurse left the room and the man looked up ‘So you come to my daughters wedding and ask me to kill a man’ he said in

a dry cackling voice. &#65533;Look&#65533; he continued, pointing at the screen, &#65533;I know that man. They&#65533;re talking about me now - listen&#65533;. The man stared at Dirk. &#65533;What&#65533;s your name? Are you one of my friends from the Internet? - Are the lambs still screaming Dirk?&#65533;

Dirk, at first recoiled in horror, then felt a sense of anti climax. So this is what they hyped up to superstar status on the back of their own fears of madness. Dirk was reminded of the film &#65533;A day on The Beach&#65533; where a submarine had set off to search a post nuclear World to track down a signal coming from a remote military base - only to find it was being sent by a Coke bottle half balanced on a Morse tapper. Outside the room the nurse waited for him. Because his nicotine craving had returned - and to avoid an awkward piece of dialogue - Dirk turned to her and asked . &#65533;Patch?&#65533;

Dirk took two nicotine patches from his wallet the first of which he stuck onto the inside of his arm. Stepping closer to Doctor Killfile he opened her white coat and slid his hand into the opening at the front of her dress. He pressed the patch onto her leg as close to the top of her inner thigh as he dare. She took a deep breath and then slowly breathed out. &#65533;What Bogart could have done with these things&#65533; Dirk thought to himself.

&#65533;Is he crazy?&#65533; Dirk asked tilting his head back to towards the door.

&#65533;Who knows&#65533; Doctor Killfile replied &#65533;We let him type away. He sees something on the TV in the morning and it keeps him busy all day. What he types doesn&#65533;t go anywhere it just stays on a mainframe in the basement. It can be read by anyone else in the building but that&#65533;s it. We got them all in here conspiracy theorists, racists, nationalists. They&#65533;ve created a world within a world really...&#65533; Her voice trailed away and she stared down the corridor for a while then added &#65533;So long are two things are different neither will come to be in the other and so become at once both one and two.&#65533;

Dirk gave her a puzzled look &#65533;You mean their brains are fried?&#65533;

&#65533;Fried?&#65533; Killfile smiled at Dirk &#65533;No that was Plato&#65533;. Then the smile fell from her face. &#65533;You must remember, mister, plate o...&#65533;

Yes, Porchy . . . we know you're filthy. :) Thanks for sharing.

Now, please DO continue posting as me . . . it's so lovely seeing how
you jump and twitch at my every whim. It's nice to see how you so
desperately hump my leg for diversion from your pathetic, abusive life.
:)

Now POST, Bitch!! POST!!!

Mike Corley FAQ
version 0.1
first edition 5th May 1996
last updated 5th May 1996
Iain L M Hotchkies iain@XXXXX.demon.co.uk

Mike Corley is a 'net personality' who has been active on the following
newsgroups (uk.misc,uk.legal,uk.politics,uk.media,soc.culture.british)
since....? Well, at least as far back as the summer of 1995.

He posts long tracts, the tone of which approximates that which one
might expect from a reasonably intelligent paranoid schizophrenic.

No details are known of Mike's 'real' personal life or background.
Once would presume that he came from a reasonable family and was
reasonably well educated before the first symptoms of schizophrenia
began.

Schizophrenia: Clinical features
(from the Oxford Textbook of Psychiatry, 2nd Edition)

The acute syndrome

Some of the main clinical features are illustrated by a short
description of a patient. A previously healthy 20-year-old male
student had been behaving in an increasingly odd way. At times he
appeared angry and told his friends that he was being persecuted; at
other times he was seen to be laughing to himself for no apparent
reason. For several months he had seemed increasingly preoccupied
with his own thoughts. His academic work had deteriorated. When
interviewed, he was restless and awkward. He described hearing
voices commenting on his actions and abusing him. He said he
believed that the police had conspired with his university teachers
to harm his brain with poisonous gases and take away his thoughts.
He also believed that other people could read his thoughts.

This case history illustrates the following common features of acute
schizophrenia: prominent persecutory ideas with accompanying
hallucinations; gradual social withdrawal and impaired performance

at work; and the odd idea that other people can read one's thoughts.

In appearance and behaviour some patients with acute schizophrenia are entirely normal. Others seem awkward in their social behaviour, preoccupied and withdrawn, or otherwise odd. Some patients smile or laugh without obvious reason. Some appear to be constantly perplexed. Some are restless and noisy, or show sudden and unexpected changes of behaviour. Others retire from company, spending a long time in their rooms, perhaps lying immobile on the bed apparently preoccupied in thought.

The speech often reflects an underlying thought disorder. In the early stages, there is vagueness in the patient's talk that makes it difficult to grasp his meaning. Some patients have difficulty in dealing with abstract ideas (a phenomenon called concrete thinking). Other patients become preoccupied with vague pseudoscientific or mystical ideas.

When the disturbance is more severe two characteristic kinds of abnormality may occur. Disorders of the stream of thought include pressure of thought, poverty of thought, and thought blocking. Thought withdrawal (the conviction that one's thoughts have been taken away) is sometimes classified as a disorder of the stream of thought, but it is more usefully considered as a form of delusion.

Loosening of association denotes a lack of connection between ideas. This may be detected in illogical thinking (knight's move) or talking past the point (Vorbeireden). In the severest form of loosening the structure and coherence of thinking is lost, so that utterances are jumbled (word salad or verbigeration). Some patients use ordinary words in unusual ways (paraphrasias or metonyms), and a few coin new words (neologisms).

Abnormalities of mood are common, and of three main kinds. First, there may be sustained abnormalities of mood such as anxiety, depression, irritability, or euphoria. Secondly, there may be blunting of affect, sometimes known as flattening of affect. Essentially this is sustained emotional indifference or diminution of emotional response. Thirdly, there is incongruity of affect. Here the emotion is not necessarily diminished, but it is not in keeping with the mood that would ordinarily be expected. For example, a patient may laugh when told about a bereavement. This third abnormality is often said to be highly characteristic of schizophrenia, but different interviewers often disagree about its presence.

Auditory hallucinations are among the most frequent symptoms. They may take the form of noises, music, single words, brief phrases, or whole conversations. They may be unobtrusive or so severe as to cause great distress. Some voices seem to give commands to the patient. Some patients hear their own thoughts apparently spoken out loud either as they think them (Gedankenlautwerden) or immediately

afterwards (echo de la pensee). Some voices seem to discuss the patient in the third person. Others comment on his actions. As described later, these last three symptoms have particular diagnostic value.

Visual hallucinations are less frequent and usually occur with other kinds of hallucination. Tactile, olfactory, gustatory, and somatic hallucinations are reported by some patients; they are often interpreted in a delusional way, for example hallucinatory sensations in the lower abdomen are attributed to unwanted sexual interference by a persecutor.

Delusions are characteristic. Primary delusions are infrequent, and difficult to identify with certainty. Delusions may originate against a background of so-called primary delusional mood - Wahnstimmung. Persecutory delusions are common, but not specific to schizophrenia. Less common but of greater diagnostic value are delusions of reference and of control, and delusions about the possession of thought. The latter are delusions that thoughts are being inserted into or withdrawn from one's mind, or broadcast to other people.

In acute schizophrenia orientation is normal. Impairment of attention and concentration is common, and may produce apparent difficulties in remembering, though memory is not impaired. So-called experiences result from illness, but usually ascribe them to the malevolent actions of other people. This lack of insight is often accompanied by unwillingness to accept treatment.

Schizophrenic patients do not necessarily experience all these symptoms. The clinical picture is variable, as described later in this chapter. The table below lists the most frequent symptoms found in one large survey.

The most frequent symptoms of acute schizophrenia (World Health Organization 1973)

Symptom Frequency (%)

Lack of insight 97
Auditory hallucinations 74
Ideas of reference 70
Suspiciousness 66
Flatness of affect 66
Voices speaking to the patient 65
Delusional mood 64
Delusions of persecution 64
Thought alienation 52
Thoughts spoken aloud 50

Various theories exist about Mike Corley:

1) he exists and is disturbed and has net access and for reasons uncertain spams a selected number of newsgroups on a regular basis - if you are reading this FAQ then you will almost certainly have seen one of his posts.

2) Mike Corley is a 'virtual schizophrenic'. Mike displays the relevant features so well that some people think he may be a construction of one or more people with intimate knowledge of mental illness and the mentally ill. Perhaps they wish to monitor the effects on the internet of the posts of a schizophrenic. Moving into X-Files territory a bit, ourselves, here.

Mike's posts attract different responses:

1) cruel, humourous, dismissive posts from those who've seen his posts many times and have become generally irritated by his behaviour while accepting that he probably has a mental illness.

2) posts from Corley-newbies - those who have come across relateviely few of Mike's posts. These may be humorouous or disbelieving.

3) posts from people who have been sucked in (for one reason or another) into Mike's Wild & Wacky World (TM)

That's enough for now.

An electron does not always give rise to just one photon, or any
photon, or a photon of the same energy.

Cloud indeed. This is like a sack of magic beans in exchange for a
cow.

Is this ill-discussion of photons the legacy of image theory? It is
like preening in front of a conjugate mirror.

This is true. But in an amateur transmitter driven
antenna system, the great majority of radiated photons
are coherent with the transmitting frequency. Coherent
photons are required to have the same energy level. The
photons coherent with the transmitting frequency are
first order effects. Assuming one is not close to
another transmitter, the photons not coherent with
the transmitting signal are Nth order effects.

Do you really want to go there? :-) According to QED, you first need
to find some negative energy photons. Then you need to get them to
propagate backward in time and subsequently interact with electrons.
Then, the electrons can then move forward in time and emit positive
energy photons while conserving momentum.

Dear Merrium Webster,

On behalf of a friend of mine, please consider adding this definition
to your dictionary:

paraphrase - to restate text in different form such that it conveys
unintended meaning

Cross-posted to:
it.discussioni.geometri,it.comp.giochi,rec.radio.amateur.antenna,hr.rec.glazba.snimanje,alt.consciousness.4th-way

Persecuted by the Security Service

Since June 1990 the British security service MI5 has waged a campaign of harassment against a UK citizen,
through the broadcast and print media, verbal abuse at work, and molestation in public and during travel.

Despite widespread knowledge of the campaign in the UK and discussion of its characteristics on Usenet for
over three years, it continues today both in Britain and North America. Its cause and basis is xenophobia
on the basis of the genetic accident of mental illness, coupled with discrimination against an inferior
"foreigner" whom they condemn as "not up to British Standards".

If this is your first visit to this site, please read the FAQ first. Feel free to contact the author with
any questions.

Frequently Asked Questions article outlines the parameters of the persecution. Who is involved, and why?
What technical and social means do they employ? What response have I made, and why has their campaign yet
to be exposed?

The UK Security Services which are believed to be behind it all. Domestic security is the province of MI5
while the secret intelligence service MI6 combats foes (and its former employees) on foreign shores.

Usenet archive chronicling the (sometimes very enthusiastic) exchanges which have taken place on UK-local
newsgroups since May 1995. Make your mark on the continuing discussion!

Believe it or not, a few items of evidence have been recorded. Although none of them is particularly
conclusive, by presenting them I hope to explain what I understand from some television and radio programmes.
Most of the "clinching" material was aired in 1990-92, and no recordings exist now, which is quite unfortunate.

My complaints to the BBC and MI5 (via the Security Service Tribunal and Interception of Communications Tribunal),
and their response to my challenges, are recorded here. Basically they deny everything, they have put their

denials (mostly - Buerk and Lewis refused) in writing, and I don't believe them. Part of the website also
documents media coverage of my campaign to expose the persecution.

Faxed articles to, and responses from British organisations including Parliament and UK media. Over 24,259 faxes
in all were sent from 1998 to 2000. Their aim was to boot discussion of the persecution into the public domain,
and that aim was not accomplished.

20,000 Reward Offered to Expose the Conspiracy

I am making a pledge for information directly leading to the exposing of the "BBC Newscaster
Conspiracy". The exposing would specifically need to lead to a legally binding admission from Martyn Lewis
or Michael Buerk of the BBC they they were watching me through the TV set.

I would be happy (delighted, in fact) to pay GBP 20,000 sterling in reward for the above admission.

That's the point I was trying to make. One cannot correctly
say "the radials are a reflector" or "the radials are non-
radiating". The radials are partially reflecting,
partially absorbing, partially radiating, and partially
non-radiating based on a level of probability for each
of the possible events which are not necessarily limited
to those four events. It's not a 100% either/or situation.

The original mirror Vs radiation "argument" between the
authors is like arguing whether gray is black or white.

at first, it seems it is the same, but in fact there are some slight
differences, and it explains the difference in gain and radiation
resistance.

> Though you might use the term GPA to refer to a quarter wave monopole

fine this page on ground planes Chuck

I thank you and everybody who tried to help me in understanding the
phenomenons with ground plane antennas.

with GPA = a vertical pole and four radials, it appears that:

-the vertical patern of a vertical dipole is not quite identical; it is
difficult to see on the graphs, but it is different, so the gains are
slightly different
-four radials are not a perfect plane (not a surprise!)
-the radiation resistance is low, 22 Ohms in free space, consequently the
losses with a real ground are greater than with 36 or 72 Ohms
-with my 40m GPA, the efficiency falls to 56% at the ground level (half the
power to warm the ground...);
to reach 90% the antenna must be ten meter above the ground, or use a
multitude of radials.

very pleased with this newsgroup, despite the difficulty, for me, with
english.

I am sorry to hear about W9INN becoming SK last year and wonder if
someone is now selling his line of antennas?

I have used one of Bill's antennas for years and it may need to be
replaced. I added extra wires for 10 MHz and 18 MHz and it loads all
WARC bands as well as six meters. Since Bill did not believe in balans
his antennas would accept all the power you had with no problem.

Bill and his W9INN antennas are missed

If you model a vertical connected to perfect ground, you should get almost exactly half the impedance of a dipole of twice the length in free space, with the same radiation pattern except 3 dB greater in amplitude and of course with the lower half missing. If you use an odd number of segments and a single source for the dipole, there will be a small difference because of the difference in source placement between the dipole and vertical. This difference will become less as the number of segments is increased in both models.

However, you can make the models virtually identical by using a "split source". Here's an example you can even do with the demo program:

Open the EZNEC example file Vert1.ez or d_Vert1.ez. Click Src Dat to see that the source Z is 36.65 + j2.971. (It's using MININEC type ground, so the source Z is the same as for perfect ground.) Then change the Ground Type to Free Space. Add a second wire with end coordinates 0, 0, 0 and 0, 0, -10.3 meters, 40 mm diameter, 10 segments, to be an exact mirror image of the vertical. Then open the Sources Window and change the source type to SV (split voltage) or SI (split current) and click Src Dat. The reported Z is now 73.3 + j5.942, exactly twice the Z of the vertical. To compare patterns, you'll need to use Perfect ground for the vertical rather than MININEC type ground.

Dick -

You should measure and document the W9INN antenna that you have!

AB7SL did sponsor and host the W9INN web pages and documentation,
BUT I have not seen this on the Internet -- since Bill passed away in 2004

w9gb
==========

William Fanckboner, W9INN, SK: William E. "Bill" Fanckboner, W9INN, of Mt Prospect, Illinois--the proprietor of W9INN Antennas -- died July 30, 2004. He was 80.

W9INN Antennas will die with him. "He did all of the work by himself, so it is effectively out of business," said his daughter, Robin Randall. "He was the business."

Refunds were mailed by the family to those with existing orders when Bill passed away.
An ARRL member and supporter, Fanckboner turned his talents for radio and electronics into W9INN Antennas some three decades ago after working for Motorola, and he was a regular QST advertiser.

Fanckboner designed and hand-built custom antennas, including the MPD-5C-78, MPD-2 and MDX-8C "hideaway" dipoles, and, his daughter says, he was working full time until a week prior to his death. Fanckboner enjoyed a reputation within the amateur community for skilled workmanship and a friendly, helpful manner. A memorial service was held August 9.

The family invites memorial donations to the American Cancer Society.

That is the correct result. The pattern is exactly the same as half the pattern of a vertical dipole, which has a maximum at zero degree elevation angle, except that the gain of the vertical is 3 dB greater because the same power is concentrated in only one hemisphere.

It is said that the elevated radials are an artificial ground plane, simulate a ground plane, form a virtual ground plane, or approximate a ground plane. It may be that the radials perform the same function as a ground plane, but do not form a real ground plane.

For example, the Butternut antenna manual at following web address says that elevated radials are an artificaial ground plane.

http://www.bencher.com/pdfs/00361ZZV.pdf

What functions do the radials perform that are the same as a real ground plane? What similarities are there between radials and a real ground plane?

How is the monopole antenna system connected to the
real ground plane - as opposed to an ideal infinite
conducting plane? What about radials buried inside
the real ground plane?

I was cleaning up today and came across an old dummy load I had that looks like it is made from 2 watt resistors. ITs mounted on a quart size paint can lid and looks to be a 50 watts worth of resistors. This looks like it may have been a commercially built unit and I was wondering what the power handling capability would be if the resistors were submerged in mineral oil.

Jimmie

Hi Jimmie, It would probably take a kilowatt, the question is for how long? I was looking at my old Heath "Cantenna" manual and it says it will take 1000 watts for about 1 minute in mineral oil. The resistor element appears to be ~50-100 watts. The Cantenna is in a gallon paint can. If none of the 25 resistors "fuse" out due to current, your load should take a kilowatt for at least 15 seconds, and take 100 watts ~forever.

Thanks Gary
Would it be worth my while to remount it for a gallon container. I was
thinking of doing this anyway because the local paint store sells gallon
paint cans, Im not sure about he avaiability of the quart size cans. I have
access to lots of mineral oil. At work we use about 100 gal a year and I can
have all the used oil I want

Simple observation of the wandering usage through that document would
inform most that "ground plane" is a term of convenience.

>What functions do the radials perform that are the same as a real ground
>plane?

There is no such thing as a "real ground plane."

>What similarities are there between radials and a real ground plane?

None.

That certainly beats going into a drug store and buying the 8 or 10
bottles of mineral oil I needed to fill up my Cantenna back in olden
days :-) Strange looks at the check out counter...

Hmmm, what is used oil? Used engine oil is regarded as carcinogenic in
these parts, hypoid gear oils similarly whether used or unused. Further,
it is full of conductive particles that may affect the load's its
performance, water and metals that may form corrosive products, and
possibly volatiles that will "boil off" when heated.

I don't know what automatic transmission fluid costs in your part of the
world, but here it is not an unreasonable cost to fill a load with new

ATF. Air tool oil is a source of light grade mineral oil that does not contain detergent agents.

Long time ago, I favoured refrigeration (compressor) oil for filling loads, but it is expensive, and the low moisture quality is soon lost if the load is not as good as hermetically sealed. It is possible to do that, I still have a load that I made using a hermetically sealed BNC connecter (yes, a true glass seal) and the whole enclosure was brazed / soldered up, closed like a 'fridge. I also experimented with refrigerant in the loads, a lot more fuss and they didn't work any better than compressor oil. Today, you would not be allowed to do that with R12!

Anyway, to your original question of how much increase in power rating with oil immersion. In the long term, it is determined by the ability of the load to dissipate heat from the outside for a tolerable rise in temperature of the oil and the resistor element. In the short term, it comes down to the resistor element, and different constructions will behave differently (eg metal film vs composition).

I'm looking to build a 2m yagi, but I haven't got any money. Can I
make one out of aluminum coat hangers? I also have a 4-foot section of
1" PVC pipe laying around, and glue, tools etc.

How about a 7dB 2M Yagi for $7 -- less if you have some PVC and Welding Rods

See ARRL Article at URL:
http://www.arrl.org/tis/info/pdf/9304054.pdf

You may need to be an ARRL member to read it -- if so get a buddy who is an
ARRL Member to get it for you.

You can make one out of anything nearly. Coathangers will work fine,
but most
I see are steel, not aluminum. Aluminum would be better. Steel
coathangers
will work ok, but they rust real fast. Power is no problem. Unless
there is a
weak link with the matching device, a coathanger yagi should handle
several
hundred watts. The matching device will be the trickiest part to
construct
using hangar wire and PVC. Would almost be easiest to design the yagi
to have a 50 ohm feedpoint with spacing adjustments, and feed with a
normal split
driven element. I'd add a coax choke for decoupling the feedline.

I used to work on some fron cooled equipment. When the equipment got hot the freon boiled and the vapor went up pipes into a radiator where it was cooled by fans then driped back down the pipes. I guess you could do a dummy load like this too.

I have a couple of the glass BNC connectors, I think they are like the ones you are talking about. They are bulkhead connectors female on both sides. I keep them around because I have never seen any others like them. They are isolated. the shield doesnt connect to the mounting flange.

Varying the parameters of the free space vertical, reading the EZNEC
help file and computing various scenarios with the G4FGQ program
RADIAL_3 has satisfied my curiosity for the moment.

I will next look at the physical problems of erecting a vertical for
use on 40/80/160.

Initially I will start with my 28 foot radiator over a radial field of
16 seventy foot radials fed with the SG-237 tuner. If I can work out
the matter of keeping that up with acceptable guys I can step up to a
48 foot radiator out of my existing aluminum supply. Based on that
experience, I will consider buying a little more aluminum to get to
the 66 foot height. That is the reason for the 70 foot radial length.

Most of the problems will be mechanical for a while.

There is a set of plans on the `net for one made of an old, broken tape measure. The pieces of the tape measure are glued / screwed to a length of PVC, and the Coax was soldered / screwed to the drive elements.
If you have this stuff laying around, and you sound as you do, then this would be a free-bee for you. My friend made a three element version, and it worked surprisingly well with about 7 dB gain. With the flat, razor thin but wide, flat elements, the pattern was very direct. It looked a bit funny, but hey, the darn thing works like a champ!

You could go to your local Radio Shack and look for a scanner antenna. They
have a small vertical with 3 eleament ground radials.
I bought one for $11 in the bargin bin for a new ham in my area..
You can even use it to transmit on 2meter band (after your legal)

I think that most here know that even the best (rubber duck type antenna) is still only 1/2 of a real antenna (no real ground plane) and adding a wire, hanging off the ht and connected to the outside of the antenna connector improves performance.

What I was wondering is.

Has any one tried doing the same thing with something like foil tape going around the outside of a HT? Or possibly a spring or a couple of springs connected to the antenna connector?

Btw it's a 5w Icom T2h so its pretty big for an HT, I commonly get in areas where I can key up the repeater of choice but skip in and out sometimes. My only other choice would be a small yagi (kind of hard to fit in a suitcase)

Thanks

Haven't tried the tape or spring ideas. But a half wavelength antenna is
a good solution for an HT because it doesn't depend on the HT and your
body to be the other antenna half.

So what is wrong with a 19" monopole sticking up and
a 19" tiger tail hanging down for 2m operation?

You might try taking a telescoping whip, and adjust it to about 1/2
wavelength at 2 m. Then use a rubber band at the center of the whip to
fasten it to the talkie just below the rubber duck. In effect this gives a
"ground plane" antenna, but with only 2 radials. For 4 radials, use two
telescoping whips.

You may not need the gain of a yagi but could still easily do a collapsible dipole that would fit your briefcase. TV rabbit (aka "bunny") ears come to mind as a donor antenna -- replace the twinlead with 50 ohm coax (and a choke balun). And for a portable antenna with a short feedline, RG-174/U is mighty convenient (buy a BNC-to-whatever patch cable & snip off the uneeded end). If you buy a longer BNC/BNC patch cable, you can cut it in half and make two (different) antennas.

Others presented good ideas. Ya know, an old TV antenna would make a decent yagi for 2m, and with people going to cable/satellite TV, you could probably find one for nothing or only a few dollars. Remove the elements you don't need, cut the remaining elements down to length, do a little rewiring as needed, connect your feedline, and you're good to go. If you want vertical polarization, redrill the boom-to-mast mounting holes 90° from original.

I once did something similar with a 3 element 11m yagi... in about an hour or so including tuneup time, I turned it into a gamma-matched 6 element 2m yagi. I used my VSWR-protected 2m rig's output indicator to indicate proper tuning by adjusting for maximum relative forward power.

Forgot I had used TV rabbit ears during a month long stay up in Syracuse.
The TV was on cable but still had the rabbit ears that cme with the TV.
These were made for use with coax so they are just a cable connected to the
telscoping antenna. Bought an F to BNC adapter at Radio Shack and was in
business. Ive used pieces of wire pinned to curtains.

The coaxial cable was likely a 75 ohm variety... but would be close enough
to 50 ohms so the rig would drive it. Apparently, it did for you! ^5

I actually did very little with them. I didnt have my ticket yet. I put a couple up in the attic for local TV that wasnt on cable. Still use them when a storm takes the cable out.

YEah, the cable on the antenna was pretty short, not more than a foot.
Fortunately I had a 6ft piece of rg58 with BNC connectors.

476. Re: Yagi question

Ok, here's what I tried. I cut notches in that 4' piece of PVC and cut clotheshanger wire to the lengths found at this calculator:

http://www.csgnetwork.com/antennae3ycalc.html

This I stuck out my window on an aluminum pole (cinderblock walls are bad). I'm suspicious of my wiring- I used very thin speaker cable to connect a ground to the screws on my light switch plate, and to the coax going into my radio. It doesn't perform half as well as my current antenna- a mobile 5/8 dipole on the end of some eye-bar with clothes-hanger groundplane radials. Guess I just need to wait until I have some real coax, the speaker wire is probably the weak link here? Maybe I was just pointing this yagi away from the station I was listening to, I suppose it would be doing its job then!

Checking almost hourly for that license on the internet!

Nelson Blaha

I'm sure it's not much of a performer, nelson. If you're using speaker wire as your feeder, it's going to be horribly mismatched. Your trx expects to see 50 ohm on the antenna, and (though I'm not certain) I'd be willing to bet that your speaker wire is either much higher or much lower. At best, this will give terrible performance. At worst, potentially blow up the output stage of your rig.
RG58 is the coax you need. It's cheap, sometimes free. It's the same stuff old 10base2 networks used to be wired with, so a visit to a dump will probably turn up loads.

He did say he was using coax, the speaker wire was just a ground, which
won't really be doing very much at vhf, so that is not the problem.

485. Slim Jim vs. EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-22 19:09:28 UTC
From: RST Engineering <jim@rstengineering.com>
Message-ID: <PZ7th.8$qI.153751@news.sisna.com>
Source record: 46748

I tried simulating a Slim Jim in EZNEC and did NOT get the expected "aim at the horizon" low-angle radiation simulated pattern. I got instead the standard "hole in the donut" that you would expect from a vertical dipole and a rather fat true donut shape rather than the expected pancake pattern.

I'm not at all sure how to connect a "voltage source" driver at the tap point without being able to simulate the ground of that voltage source tapped up from the bottom end as well.

Thoughts?

Jim

Yes, I'd worry a little about grossly overdriving carbon composition resistors because of the thermal resistance between the heat-dissipating composition material and the oil. There's going to be a temperature gradient across the phenolic case that might be considerable -- in other words, the resistance part could be much hotter than the oil. Resistors which have the actual dissipating portion very close to the outside, like film or (noninductive) wire wound resistors would be much better in this regard. If you overstress carbon comp resistors you'll typically get a permanent change in resistance. If the overstress is extreme, they'll crack, explode, or catch fire. Make sure your oil and container won't present a hazard if this happens.

You should have a wire across the bottom of the antenna at the tap
point. The voltage source is in the centre of this wire. A real Slim Jim
would be fed with a balun so both halves of the matching section are fed
symmetrically.

This however won't change the radiation pattern. There's nothing magic
about a slim jim, it's just a voltage fed folded dipole so the radiation
pattern will look like a dipole.

Thanks Roy, I too have given this some consideration and am thinking of rebuiding the dummy load with metal film resistors heeping the brass buss bars that came with the load. The actual measure DC resistance is near 60 ohms so I suspect some damage has already occured. The resistors have no markings but I figure 220 ohms each. Its difficult to count the resistors the way they are arranged. You dont pay 3 bucks for something like this at a hamfest and expect it to 100%.

Hi Jim,

This is the problem of the variability of matched, halfwave antenna
results in life too. Most antennas are connected to coax drives, and
are not excited by point sources. However, you are not asking about
the complexities of uncoupled lines even though we get their
complaints here all the time.

>I got instead the
>standard "hole in the donut" that you would expect from a vertical dipole
>and a rather fat true donut shape rather than the expected pancake pattern.

I would argue that your expectation would defy both experience and
analysis. Of course, just what a pancake pattern means leaves open a
lot of interpretation. Myself, that would mean to me to be an
especially high gain.

One of the wild cards of analysis which can really skew the numbers is
how you choose the height above ground. The patterns tend to exhibit
a mud puddle splash achieved when you jump in with both feet.

>I'm not at all sure how to connect a "voltage source" driver at the tap
>point without being able to simulate the ground of that voltage source
>tapped up from the bottom end as well.

I presume this tap is across the match section. Just make it a short
wire connecting to both the short element and the long element, with
the source in the middle segment of the short wire. Voltage, current,
or power source driven is not going to matter at all to the results.

Yet most folks experimental results seem to show a radiation pattern
squirted a lot towards the horizon and very little up and down.

That's the way I explain it to my freshman electronics classes. You have a given amount of dough. You can either make it a donut, with radiation fairly equal in all directions except up and down, or you can squish it into a pancake and aim it where you want it to go. I then go on with the garden hose analogy of a sprinkler versus a nozzle, and totally confuse them.

All,

I am interested in experimenting with ferrite core receive antennas. I have about a dozen .4 by 10 inch rods. The primary band of interest is 75m. My question is:

1. For best reception is it better to make a fat or a long antenna? I cannot find much written about these antennas and have not found any equations.

The literature states the efficiency of these antennas can range from a 10**3 to 10**6 a dipole of the same size. Let's not argue the high end but accept the low end for discussion. Does this ratio refer to length or diameter?

Is there a good primer source? I have the ARRL Antenna handbook.

Thanks - Dan

I seem to recall that this is a design problem often treated in texts. Certainly Kraus has a treatment in his book.

In the Fig 3 in my article http://www.vk1od.net/SmallUntunedSquareLoop/index.htm , I give the formulas for calculation of the o/c voltage in a single turn loop in air. In the case of a ferrite loop, the area will be the csa of the loopstick, and you will have to multiply the single turn value by the number of turns and include the effect of relative permeability of the ferrite. You can then proceed to work out the source impedance for the ferrite coil and the loaded voltage (including the effects of tuning if used).

Is efficiency a good indicator of the "goodness" of a rx antenna where the ambient noise is high (as it is on 80m)?

Perhaps if you want to receive normal signals, you just need an antenna that will deliver 6dB more noise (ie from ambient noise) to the receiver than its equivalent internal noise. In that case, the received S/N will not be more than 1dB worse than with a lossless antenna system.

Actually, I'm sorry to say Jeff was right. For the sake of experiment
I had connected with speaker cable more than just the ground.
Basically, I connected speaker wires to the contacts on my mobile NMO
mount. The NMO mount had coax running back to the radio. I knew
transmitting like that was a pretty bad idea (illegal anyway), and that
I needed to get a proper wiring eventually, I just wanted to see if I
could observe the directional effects of my yagi.

Oddly, though, my Alinco DR-130 came with a CB MAGMOUNT when I bought
it as a kid used. It even survived my keying it attached to that
thing, and I don't think it has any protection against high SWRs. I've
always wondered how my radio survived that. Maybe it didn't... I'll
have to test it when my license comes. I only think it works now
because I tried it a while back on MURS frequencies with a radio shack
scanner.

Hi I remember about 30 years ago I needed a directional 2 metre antenna
in a hurry.
Came up with a good old Kiwi #8 fencing wire solution. using an old
ceramic "choc block" connector for the feed I madea 2 element cubical
quad on a bit of 2x1 timber. (Usual formulae out of the ARRL and RSGB
books). Despite being made out of galvanised Iron wire it showed a 7 dB
gain over a dipole at the same height on the local 2M beacon!
Where there's a will there's away!

Andy writes
A good point..... The rule of thumb I have always used is that if
you turn up the receiver to hear the noise, and THEN connect the
antenna,..... if the noise level goes up a lot, then everything is
working just fine..... At HF, it isn't unusual to have 30uv/m of
"noise", from cosmic or galactic or whatever... A 20 db noise
figure is just fine for a receiver in those ranges..... The biggest
challenge is man-made interference .....

I have seen several articles using ferrite loops at HF, mostly
for building direction finders.... If the ARRL handbook has a
heading under "direction finders", or Hints and Kinks, or
the ARRL Antenna Handbook, they can give the OP some ideas....

Dan,

Some more information on expected ambient noise per ITU-R p.372-8 is in my article at http://www.vk1od.net/fsm/FSAmbientNoise.htm . For 3.6MHz, it is probably wise to expect ambient noise field strength somewhere around 6dBuV/m in 2kHz bandwidth in a residential environment. If an antenna can develop more than about -130dBm in the receiver from that field strength, the S/N should be ok on most modern SSB receivers which have a noise floor somewhere around -136dBm. If you were in a quieter environment, you would benefit from a better antenna.

Hi Jim,

Most folks, and many more sophisticated folks lack the skill to really confirm this. It takes 10% tools and 90% common sense. Most can afford the tools. The rarer common sense (which includes experience) again informs us that height above ground makes a considerable difference in results which are often mis-ascribed to a "revolutionary" design.

One need only examine your statement about comparing "towards the horizon" to "up and down." I dare say very few can accomplish FS measurements of any accuracy in the far field above 50 or 60 degrees (and not simultaneously create a situation that abounds in reflections off the platform they are using to achieve that elevation).

Successfully challenging these claims of superior performance is easy, unfortunately making these claims is far easier. Worse yet are these claims satisfy the dreams of wish fulfillment. We are regularly submitted to glowing reports of such dreamers who refuse to consider the aridity of fact and testing. One such is a designer of 9 foot radiators for 160 Meters. His antenna design, too, has excellent performance towards the horizon. One need only look at the list of testimonials any one of which negates science.

>
If the feedline continues vertically downward from the antenna (J-pole or Slim Jim) then RF current will flow on the outside of the coax, and the feedline will both radiate and receive. A common-mode choke or current balun (same thing, different name) at the feedpoint will largely prevent this.

If you don't deliberately include the feedline in the model, you see only the pattern of the antenna itself - it's like having a perfect feedline choke. The difficult part of antenna modeling is to include a realistic model of the feedline... and most people don't do it.

>>
>> This however won't change the radiation pattern. There's nothing magic
>> about a slim jim, it's just a voltage fed folded dipole so the radiation
>> pattern will look like a dipole.
>
That's not quite true, for two reasons. An end-fed dipole has a slightly different pattern from a centre-fed dipole, because the current distribution is slightly different (one end has the feed current flowing into it, while the open end has zero current). Secondly, the currents in the two arms of the feed stub do not completely cancel. This leaves some common-mode current in the stub, which will radiate and modify the pattern of the dipole.

These real differences from a dipole tend to tilt the radiation pattern upward, even in free space. Variations like the Slim Jim are aiming to bring it back down towards the horizon... but there's very little evidence that actually happens.

>Yet most folks experimental results seem to show a radiation pattern
>squirted a lot towards the horizon and very little up and down.

The patterns of simple antennas are extremely difficult to measure - it needs accurate level measurements and also a very large test area which is completely free of reflecting objects (including the experimenter himself). Amateurs can meet the first of these requirements, but not the second. G2BCX, the original developer of the Slim Jim, did have some

measuring facilities, but he still had to work in his own backyard.

Another major source of errors is that most experimenters fail to use a choke balun at the feedpoint, so they are also measuring the radiation from some undetermined amount of feedline.

What "folks' experimental results" most often consist of is changing the antenna and checking how well it hits some distant repeater. That's fair enough, but it tells them less about the antenna than they believe. For a start, the new antenna will be in better physical condition... and then very few people can resist the temptation to make a few other improvements at the same time, like replacing the old coax and re-making all the connections.

All those practical things can make much bigger difference than the basic antenna design.

The differences between any of the J-pole variant designs are really too small to be worth arguing about. What makes ALL the difference is the engineering - how these designs are brought to life.

Hello Jim,

I think your simulations are right.

As the height of the Slim Jim is about 0.75lambda (common mode choke in coaxial line, to avoid radiation from cable), the beam width in vertical direction is limited by physics (will be similar to a dipole). If you want an omni-directional pattern with small beam width in the vertical plane, your antenna's vertical dimension must be large with respect to wavelength (for example co-phases dipoles, full wave dipole, 1.25lambda dipole).

About the Slim Jim
The upper half wave section (with the fold back HW section) just acts as a single end-fed dipole with current maximum in the middle. The current in the two HW sections is in phase. The lower quarter wave section acts as a matching circuit to transform 50 Ohms to a high impedance to feed the dipole section. The current in both quarter wave legs are opposite to each other and therefore has little influence on the overall radiation pattern. There is a small common mode current in the quarter wave section (just as in a normal end-fed HW dipole without radials, like is done in many Citizens Band antenna's).

The two wires of the HW section are too close to each other to have significant impact on the radiation pattern in the horizontal plane (so it will be omni-directional).

If you want to simulate the effect of cable radiation, just put the voltage source at the points where you want to connect the coaxial cable. Draw a wire (that is the screen from your coax) and connect it at the voltage source (where the screen of the coax will be connected). Now you can see the common mode current in you coax and the change in

overall radiation pattern.

Best Regards,

Wim

> > -
> > - -

Hello Camelot,

Directivity is determined solely by the antenna structure. I dipole has a directivity of about 2.14 dB, no matter from what impedance you will feed it. Be carefull that in many cases the feedline will carry common mode current and will radiate too. If so, you must model at least the screen of the feeder as part of the antenna too.

Directivity is strongly related to the radiation pattern of the antenna.

If the match is perfect and there are not heat losses, directivity = gain.

Efficiency is the ratio between total radiated power and real input power (always less then 1). Efficiency is limited by heat losses in conductors and dielectrics.

In general: gain = directivity - (mismatch loss) - efficiency.
All in dB.

So if you have an antenna with a maximum directivity of 6 dBi, a VSWR=2 and efficiency = 0.5, you gain in the direction of maximum directivity is 6 - 0.5 - 3 = 2.5 dBi.

>From the input impedance you cannot say something about directivity. For example, look to a HW dipole, it has about 50..73 Ohms. A folded dipole (with same radiation pattern and hence same directivity) has about 200 to 300 Ohms input impedance.

About the effect of the middle ground port.
When the output of your RF chip has good symmetry, and your antenna will have good symmetry too, the RF current into the middle port will be negligible. A decoupling coil or capacitor may have a small effect on resonant frequency of the antenna (because of small capacitive coupling to the actual antenna). The change in input impedance will be minimal/negligible also.

If you might expect asymmetry, using a capacitor to ground, will cause (significant) current through the capacitor and hence will affect radiation pattern, input impedance, etc.

Best Regard and good luck,

Wim
PA3DJS.

The only work I've seen done on multiple ferrite rods was for use at
the AM BCB frequency and they bundled them side by side for a short
fat antenna.
IIRC the information was in an NRC (National Radio Club) publication.
I think you will find an index of their publications online.

How about some real math and equations. You should present some technical basis for your conclusions other than some verbal handwaving.

You also seem to make some assumptions which are irrelevant (parallelism being good for manufacturing being one) that may not be valid.

You are looking for open minds, but present nothing of substance.

Art:

I take the thrust of your previous text to say, "We have lost focus of the antenna as a technical device. Some now think of it as a "magical device" and some as a "work of art." I can see some truth in all of that. Plus, I will go further, if anyone thinks we have discovered ALL there is to know about antennas, they are simply wrong ...

Basically, I only have use for three types of antennas. Two of these are for terrestrial use only and one is for non-earth use ("talking" to satellites, NOT aliens.)

Of the two for terrestrial use, one is omni directional the other VERY directional. Now omni is quite easy, most dipoles or monopoles can be placed to work with varying success.

So that leaves the "beam" or directional antenna. Now, the best directional antenna I have EVER found is the parabolic dish--there just ain't any better! However, for HF (indeed vhf/uhf are VERY difficult to construct) these are out of the question for most of us. So, the question becomes, "How can we mimic the performance of the dish with practical materials.

Now, that is what we are all looking for, isn't it?

Warmest regards,
JS

Getting a patent merely proves that one is able to hire a competent enough patent attorney to convince the patent examiners that the application in question isn't the rehash of prior patents. Enough bogus software patents are issued on an ongoing bases to bear this out. A patent is not proof of sound engineering even though the public at large has been hoodwinked into believing otherwise.

Without field strength/antenna range data, any other claims are akin to shouting in the wind. Your money doesn't matter, show us the data.

Andy writes:
Thanks for posting the website, Owen.....
My comments were based on a residential/business site with a bandwidth
that
could accomodate AM, and I was generalizing .....

When I was designing LORAN (100khz) set sfor aircraft (TI2000) , I
needed to
find how small an external whip antenna could be... It turned out that
22
inches was sufficient, since a larger antenna which would convert more
signal, would also convert, proportionately, more noise......

I guess that's why whip antennae on AM car radio are only a couple
feet long, and why loopsticks work so well at AM broadcast.....

A nice article you wrote,.... thanks for giving the web reference...

In antennas the math is the concept. No one will ever have a clue how one works without understanding the math. May I suggest that everyone hold there responses until you say all you have to say encluding posting the relevant equations with references. This will be the only route fair to you and prevent the normal bickering. Your ideas if presented in a professional maner will recive a professional response.

Jimmie

Geesh! Something we finally stand in total agreement with.

However, like most things in science, usually what we are hunting is
first "discovered" in a "practical" form, then the math is "found" to
explain, describe, and "predict" it and its "properties" ... such has
always been mankinds' lot--or, thanks for those goofy guys in their
basements with their goofy ideas ...

Still, an excellent and valid statement.

Warmest regards,
JS

If you looked at the reference material I gave you, you will see that you might expect the ambient noise in a residential environment to develop about -83dBm in a 2kHz wide rx with a lossless antenna.

If your receiver noise floor was say -136dBm (Noise Figure about 5dB, a state of the art HF receiver), and you wanted a 6dB margin to restrict degradation of the "off-air" S/N to 1dB, then your antenna needs to have gain of at least (-136 - -83 + 6)dBi, or -47dBi. That is not very difficult to achieve, even with a ferrite loop antenna.

Owen

Hi Dan,

Yes, but only insofar as it is balanced and gives you sharp nulls to
help eliminate some of the interference. This may require elevating
it away from reflecting surfaces if it is not shielded.

Hey Yuri,
Is it true, I've heard you can't operate a Razor over dry land, or
where there is flamable material nearby because of the fire hazard?

How about we put one up over a salt marsh, would that be safe enough
to not endanger the population?

Patents are almost useless unless you actually build something. Basically patents protect ideas and I know a guy who use to do hundreds of applictions on just ideas. It is not the purpose of a patent to establish that an idea is workable. It just establishes it as "your idea" Besides I thought we were talking about antennas, not the value of patents.

Jimmie.

Wow! From Hero to Zero in 12 minutes and 33 seconds.

Jimmie, you could have waited the obligatory 12 days, 33 hours and 54
thousand seconds to discover there are no facts to be had that
1. Contradict ordinary-as-mud modeling;
2. Reveal theories that would astonish the multitudes;
3. Offer a revelation of how statics can perform what dynamics do
daily. And certainly
4. No evidence of the comprehension that statics are a mathematical
fiction. Life does not allow them, and they are completely unknown
outside of a book or a classroom.

Art cannot even explain how he obtained a 50 Ohm non-reactive feed
into his five assorted wires, non of which could have possible
supported a fifth of that value (and jacked up with so much reactance
as to reject all power).

As for your first observation above about waiting. The poster is
entirely responsible for content, both its length and its purpose.
This can be as easily achieved in one posting as in 200. If the past
is to inform us of how efficiently that process has been successful;
then your cï¿½sura || is entirely justified.

How many hours did you have on this projector at failure? Part of
engineering a design is lifetime expectancy, judging by the projectors
I've seen over the past few years a three CRT projector has exceeded
it's expected lifetime.

Yes these are begining to show up in Goodwill stores.

What kind of "telecom systems"? What is the grounding for? How pervasive and destructive is lightning damage in your area? What is the soil conductivity? ...I think you get the picture.

There is no one "perfect grounding" system because there are many purposes, many requirements, and many satisfactory outcomes. You need to define your question in those terms before attempting to seek a solution. There is no "perfect grounding system for everything."

Next time I ask about something I will have it in my hand when I discribe
it. Dummy load is 44 each 2.2K 2 watt resistors in paralell.
I think I will rebuild it using metal film.

Doubt if it was a fault in engineering. If the engineers had their way it would probably be a dale heatsinked to the chassis.Often one engineering team designs it and another goes through to find out how they can cut corners.

Very, very true. Razors were designed and customized over hard clay of Scarborough, ON and I had to wait for maple leaves to fall, otherwise it was fireworks. It was also reported that if I beamed power lines, the turbines in Niagara Falls started to spin in reverse and pumping up water from lake Ontario to Erie (even Tesla could not account for this). Another effect that expert matrimorticians can not formulaed it. Wide open field for basement scientwists.

> How about we put one up over a salt marsh, would that be safe enough
> to not endanger the population?
>

Salt marshes call for different breed of arrays, we are ploting some dual (mutli really - all) polarization three dimensional arrays firing and skimming the salty perfect waves jus' like pebbles, using wave ampliphication and Van Allen Belts for reaching the dark side of un-enionosferried territories utilizing resonant freakvencies of bridges as parasited elements for local coverage of QRPeers. This will be so far out in the salty mud, that I do not consider even getting patent for it, maybe some fuzzy pictures like of Razors. Looks like we will rearange all US records jus' like with Razors I decimated all Canuk records. So get your high vaders water proofed and get in shape.

So when we see the mud a bubbling it isn't marsh gas, it's the power of the Mighty Razor beam? Skimmin' the salt marsh, slippin under the Bay Bridge, grazing the Atlantic Ocean, then blasting the ionosphere, and next stop is Europe. Smashing S meters against pegs all across Europe. Oh, yeahhhhhh, now this is living, this is what antennas are all about !!

My FCC approved antenna pattern range is the overrun area of the local airport. It is largely comprised of short weeds, rocks, and the occasional dirt patch {;-)

If it wasn't freakin' winter, I'd put the 16' wooden mast with the up-n-down mechanism for nulling out ground effects at VHF and see what the pattern of a "real" SJ is. I think I'll wait for spring/summer for something that really isn't time critical.

I hate to admit it, but the HP 608 is still the best thing I've found for accurate attenuator calibration on the range. The Systron-Donner spectrum analyzer with phase lock down to a few Hz. is the other end of the range; we have large sheets of black conductive foam to keep the reflections from the equipment to a minimum and use battery/inverter power to keep power line interference down.

As for the choke balun referred to in another post, of course we use decoupling toroids (3 of them are generally sufficient) where the coax passes by the bottom of the antenna. Choke balun, decoupling ferrites, call it what you will.

Depends on the cost of the resistors. Prices seem to increase somewhat
expotentially with wattage so the two smaller ones may have been cheaper
than one larger. In this case the cost improver would have went for the
multiple resistors.

544. Converting From mV/m To Decayed mW (ERP)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-24 01:29:53 UTC
From: Kaimbridge <Kaimbridge@gmail.com>
Message-ID: <1169602193.749956.78390@l53g2000cwa.googlegroups.com>
Source record: 46708
Cross-posted to: sci.electronics.design,alt.engineering.electrical,rec.radio.amateur.antenna

I've seen the different conversions for mW, mV, mV/m, dBm, mostly based on 50 ohms.
What I'm interested in is converting a given field strength mV/m, at a given distance for a particular frequency, to the equivalent (decayed) baseline wattage.
For instance, in section 73.318, the FCC defines the FM blanket overload boundary as 562 mV/m (115 dBu), having a distance equalling .394 * KW^.5 (ERP), where (I believe) ".394" is supposed to be 50000^.5/562.
So, assuming flat terrain with "raw reception" (meaning no antenna and line gain/loss), what would the equivalent ERP wattage be (i.e., if you took a field strength meter and held it next to a transmitter, what would the wattage be to produce 562 mV/m?)?
Since wattge can be found from mV/m, what would the equation for decayed wattage (mW_d) be, given an ERP (KW_erp), frequency (MHz) and distance (Km)? Instead of 50, should 2*Pi*60 Hz (~=~ 377) be used for ohms?

> of telecom systems.

As another reply states, there are no such thing as a perfect ground<PERIOD>

You have to define your need of grounding. What do you want to achieve etc.

You can create a "good enough" or "adequate" grounding in conformance with your spec or demands.

A health and safety approach on grounding is not necessarily enough to secure operation in a tropical thunderstorm.

However.

The easiest way to find suitable material on grounding etc for demanding specifications is to look on how to EMP proof a computer installation.

EMP stands for "ElectroMagnetic Pulse" and is a "biproduct" - or in modern weapons, the primary product of thermo nuclear weapons.

The quest for a "perfect grounding" does not necessarily protects from EMP and EMP protection does not necessarily achieve a "perfect" ground.

Again - However... Following the strict guidelines on the "ABC" of EMP protection, you will be forced to secure such a grounding that any EM pulses or EM noise will be unable to damage your telecom equipment or systems. Even if you have a self contained ground separated from the "natural" ground, you only have to connect your floating, EMP secured ground to the natural ground. Bear in mind that the EMP protection is cancelled that way but as your intention is grounding :)

Grounding a RF installation is a different matter but I believe that you are asking for a telecom grounding rather than antenna grounding.

If they used one resistor in another place or places it's could have
been easier to use multiples in series/parallel where they could rather
than purchase and stock another value at the factory. I worked at a
place where we used 5532 op amps in many audio circuits and in one place
as a flip flop so we wouldn't have to stock a 74xx or 40xx just for that
one use. It was easier on the assemblers to have one bin of chips,
better quantity pricing, no sweating running out of one part kept in
smaller quantity, (insert more bean counter stuff...)

Art:

We may be two of the three blind men who went to see the elephant.

I know for a fact the spinning of the earth (time) has no place it our equation on radio frequency vibrations. However, I do accept the possibility of a "universal time frame" which does--but, someone SHOW it to me first!--universal time frame.

I do accept that the "mysterious 377 ohms" seems to "work" in our equations. However, I do NOT believe it is "real", but I do believe it is acting as a "mysterious placeholder" for something unknown, unseen and undiscovered by us ... and, I do not know what this is.

So, in the end, I am viewed as a kook--just like you. But, with what you have described, it only leaves me with me with more questions--at least at the present time ... I am patient, perhaps one day you find the right words and I will have a revelation ...

Regards,
JS

80 is basically useless. 3400 and 4000 I have a Pegged meter WFM signal
from 1380kc station here. I have mini harmonics ever 200kc that
basically makes 80meters unusable Its really annoying and the station
says they had their equipment recertified 2 months ago

Is there a place I can report this in the FCC?

The antenna is about 10 miles from me. And they are running 5kw.

They are planning and have approval for 50KW now and Im worried that
160 and 80 and possibly 40 could me useless.

Thanks
Scotty W7PSK.

You can simply send a letter to the FCC in Washington DC. However there might not be anything they can do.
Some years ago a radio station in Marion IN was causing interferance to amateur radio ops in the area. It seemed that there was a spur that fell in the middle of the affected ham band. When the FCC inspected the instalation they measured the spur and determined that it was below the maximum power limit for such emissions. The result was the hams had to suffer due to a totally legal emission.

This is hardly an antenna issue.

You do realize that it may not be the transmitter?

If your receiver (and you don't specify what it is) hasn't got
good strong signal-handling, the station may be overloading it
and causing the junk. And at first glance, it wouldn't be
obvious whether it's the receiver or the transmitter.

Try a different receiver.

Put an attenuator between your receiver and antenna, and see
what happens to those signals when you increase attenuation. If
it's overloadig, there will be a point where the unwanted signals
go away that can't be accounted for by the actual attenuation.

Borrow a spectrum analyzer, which should stand up well to strong
signals since it wouldn't be much use otherwise, and see what signals
are arriving at your antenna. If you do see signals that are traceable
to the broadcast station, then likely they do have a problem. But if
not, it's your receiver.

And it may not even be the receiver. There could be something acting
as a rectifier, that is picking up the transmiter signal and generating
harmonics for your receiver to pickup. A rusty rain gutter, or
a bad connection on an antenna, obviously something nearby.

You have no reason to doubt the station's word, especially since
they do have the rules to follow, and likely are in a worse
position than a ham with a bad signal. You are expecting the
transmitter to blame because you can't imagine your receiver
is at fault. But until you can actually rule out the latter,
you have no real reason to blame the transmitter.

Related, sort of:

When I was in Navy ET School in the 1960's, we had a shipboard radio transmitter lab which used banks of incandescent lamps for the dummy loads. By the time we got to that phase of the school we understood the concept of matching to 50 ohms and I wondered then (and now) what the actual impedance of a bank of light bulbs would be. (Of course it changed with the amount of power applied, since it lit the lamps more or less brightly.)

Nobody ever explained it. It's a wonder we didn't make more smoke than light. [AN/SRT-14, AN/SRT-15, for those who've been there & done that.]

Also, for excellent heat dissipation and no conduction, a liquid called FC-75 is used as a heat transfer medium. They literally immerse the gear in a tank of the stuff and run it though a liquid-to-liquid heat exchanger. It's totally inert. We used it in our high power pulse transmitters in ECM gear and it's apparently still around [http://news.thomasnet.com/fullstory/473395] . No, I don't have any :-(

Art:

Take 1.1111 Mhz. How do we know that is 1,111,100 cps?

We know that because earth makes 1 revolution in 1 day (24 hrs).
We know there are 60 mins in an hour.
We know there are 60 secs in a min.
Etc.

Now, destroy the earth, forget all about its' revolutions.

Now, what is that 1.1111 Mhz really?

If you were an alien the rf would NOT appear to change (assuming they
are "stupid" enough to base time on the rotations of their planet), what
does it look like to them? Certainly NOT 1,111,100 cps.

So, how could everyone ever agree on what that rf REALLY is?

You must give me an example NOT including the earth, else I will give
you back examples basing time on my goldfish swimming! (and he/she makes
way more than 1 revolution per/day!)

And, perhaps gravity and time are only two phenomenons of the same thing ...

In space, there is only the ether ...

Regards,
JS

Excellent suggestion. Try a high pass filter passing everything above
1710 to see if you have an improvement.

At least then you will have a good indication if it is a problem of
receiver overloading or not ...

If you are using a transceiver as opposed to a separate receiver/xmitter
(I know, I am an OT) you can use an rf switch to cut out the filter on
xmit to "cure" the problem.

Hi OM,

Must've been before they were replaced with the AN/URC-32 (Collins). I
suppose there weren't enough bulbs to load 500W (much less from about
a dozen bays). All I remember where conventional dummy loads and the
time we used the shorting bar on the finals' capacitors and took out
the island's power station (forgot to throw the power switch off).

Hi John,

My taste runs to Reggae, Electronica, Hip-hop, and Wo'pop - and the
immortal Carlos Gardel.

For violin, Papa John Creech, or David LaFlamme. To return this to
any faint resemblance of RF, I studied violin under Clarence Westphall
who called it a fiddle. What makes the connection to RF? He was the
first solo male performer on coast-to-coast radio. Hmm, something
like three or four degrees of separation in that....

I have no talent for violins, however.

I solved such a problem by receiving on separates antennas: two center
loaded verticals 3meter high and about ten meter between them.
By adjusting attenuation and phase delay between the two antennas i got a
null in the spurious direction (ground wave), but no nul for incomming
signals from correspondants because the phases after ionospheric propagation
were not constant and identical on the two antennas.
Unfortunatly I have forgotten the phasig system I used, it was lengths of
coax (WL/8) and a variable capacity, found on QST or Ham Radio at the end of
the sixtees or at the beginning of the seventees.
For attenuation it was a simple linear double pot.

> non switching power supply.

Your particular case sounds like they designed for one resistor and
designed very close to the function/failure edge, then rushed to
production only to discover the single resistor was too far over that
edge. Their solution was to quickly change the board design for four in
series-parallel but put them in the same space, since they already had
umpteen thousand resistors ordered or even in stock. It worked in test,
worked for a week or so running continuously... ship it!

> ... It would appear that I retired just in time
> before engineering studies became out of fashion

Engineering studies aren't out of fashion, in fact they're more
intensive, involve a lot more computer modeling and help push the design
closer to the function/failure edge. Not out of fashion but a smaller
piece of the pie, now the design involves a lot more
design-for-manufacture including pick-and-place instead of a human
assembler, all SMT (see previous reason), least component count
possible, limited lifetime so you have to buy a new unit in a few years,
less 'robust design' and more 'economical,' higher profit and lower quality.

Don't blame the engineers, unless they went on to get an MBA after the EE, ME, etc. I got out of private industry ten years ago for these reasons, I was tired of design reviews where management pushed the 'you can cut this out, it won't be so bad' line. Designs aren't for the benefit of the customer, they are for the benefit of the stockholder and the board of directors. What was 'The quality goes in before the name goes on,' is now 'the profit is determined before the unit is produced.' I'm not saying that profit isn't a good thing, just that it shouldn't be the overwhelming thing.

73,
W8LNA

Yeah, I am familar with the stuff, its an inert flurocarbon. FAA did some
experiments to see if it could be use in RADAR tx oil tanks to replace PCB
type oil. I understand it worked pretty good, having better heat transfer

qualities than the oil they finally used.

After I got my ham ticket I built a little TX with a 6146 and used a light bulb dummy load. To get an idea of how much power I was putting out I measure the rsistance of a photo resistor with the tx keyed then applied a variable ac voltage to the lamp and adjusted it until the resistor measured the same and calculated power from the voltage and current measurements. I wonder how accurate this was.

Hello,

The formula you should use (or propagation graph) to calculate the ERP
(or input wattage), based on field strength measurement, depends on
many factors like: Frequency, height of transmitter and receiver,
ground properties, antenna gain, etc.

The reason for that is that at certain distance from the transmitting
antenna, the ground reflected wave interferes with the direct wave.
Whether the reflected wave will result in destructive or constructive
interference depends on the path length difference and ground
reflection coefficient. At large difference, there is always
destructive interference (this causes that in reality for VHF and low
UHF, field strength is inversely proportional to distance squared).

Maybe you can give some more details about antenna type, transmitter
height, distance, frequency, etc. One formula to calculate the path

loss that incorporates ground reflection is the "two-ray propagation formula". It comes in two versions one without sinusoidal functions (the simple one) and the complete one (with goniometric functions) that also gives reasonable results when the antenna is more close to the antenna.

At large distance other phenomena become dominant (for example over the horizon diffraction).

Hope this will help you,

Wim

The radiated power needed to generate a given, free-space field strength of course depends on the length of the propagation path to that value of field strength.

Re-arranging the FCC equation to solve for the radiated power needed to generate 562 mV/m when distance in kilometers is known gives

P = D^2/0.1552

So if there is a need to limit the field strength to 562 mV/m at a location 1 km from the antenna, we see that ERP cannot exceed ~6.44 kW.

Another way of doing it is to massage this "classic" equation.

Field Strength in dB above 1 microvolt/meter =
104.77 + ERPi - 20 log (D)

where ERPi = Effective Radiated Power in dB referenced
to 1kW from an isotropic radiator
D = Distance in kilometers

It gives the same answer as the simpler equation above.

I think this will answer your question, if I understood it right.

Why all this stuff about "high pass filters" and such. You are dealing with a spot frequency, not a band of frequencies. A simple parallel resonant notch filter should do the job quite nicely and still pass everything from DC to daylight except that spot frequency.

> you have no real reason to blame the transmitter.

I used to work at a Station and I know the rules they have to follow, I also know that very shoddy
work is done at a lot and just signed off. Ill continue to check my end, but If Ive never heard the
birdies before with the same station (Save the 706MKIIG and new coax on occasion) Ive had for 18 years here
with no problems until the recent storms and the station has multiple birdies and its in Wide FM rather than
AM ... makes me wonder.

Hi Jim

There's not much more effort in completely covering a band of problems
with a band reject (high pass) filter. The original poster could
discover the NEXT broadcaster creating problems when he limited his
suppression to the first one. Who needs a chain of notch filters when
one would work as well for the entire band?

Really?

Perhaps my understanding of Einsteins theory is incorrect, or I am attempting to add a relative quality to it?

In that aliens galaxy existing far-far-away on a planet engaged in Star Wars, that cesium atom may not oscillate at that frequency at all!

Now, like that told Virgina O'Hanlon about Santa Claus--if the NEW YORK TIMES said it, it must be true--or, perhaps the editor was mistaken?; I must admit--if Einstein said it, it must be true! <half-smirk>

Hi Jimmie,

This was exceptionally accurate. The substitution method here employs
a transfer standard. By bringing the light bulb to the same light
level (the substitution), you have removed any inaccuracy of the
detector, the photo resistor. It has been removed from the sources of
error. Further, you have shifted out of the more difficult domain of
direct RF measurement into 60 HZ where there are a world of tools
(transfer standards) that exhibit very good accuracy.

This is a form of calorimetric measurement, akin to bolometery.

Hi OM,

My very first EE professor (also an engineer at the HP division in
Colorado Springs) taught us the merits of designs meeting the
expectations of Mad Man Muntz.

Muntz was a car salesman who entered the nascent field of TV in the
late 40s and would wander the design lab with a pair of dikes in his
pocket. Looking over the shoulder of any designer he would snip out
components until they lost the picture, it would roll, or the sound
would go dead. Then he would suggest they put back in the last
snipped component.

He discovered his TVs didn't need synchronization circuits because his
market was in urban cities where the signal was so powerful as to
provide enough level to be self-syncing. I know, because I fixed many
of those TVs that eventually found their way into the Burbs, and were
forever rolling unless you found the sweet spot on the horizontal or
vertical adjustment (always in the back).

Cesium by any other name would smell as sw.... no, that alludes to
Shakespeare and we know how much he gets pissed on here by
anglophobes. We'll try that again:

If it didn't oscillate (resonate actually in a magnetically biased
electron fountain) at that frequency, it's probably Rubidium. Aliens
watching first runs of 50s soap operas ("The Secret Storm" in this
case) would undoubtedly have naming problems. This is not a technical
problem; it is a cultural one.

Again, I may have misunderstood "Old Al" along then!

If that cesium atom no longer obeys your "10,214,000,000,000,000 oscillations"--"LAW", then perhaps 1,111,100 cps no longer obeys the "cps law" either. And, indeed, 1.1111 Mhz is no longer what we see at all!!!

Of course, the above must be wrong. ET did manage to call home and apparently there were able to agree on the same freq. (sure would have liked to have taken a look at "Ole ETs'" watch ...)

> attempting to add a relative quality to it?

Einstein has nothing to do with it nor does the rotation of the Earth.

"Under the International System of Units, the second is currently defined
as the duration of 9,192,631,770 periods of the radiation corresponding
to the transition between the two hyperfine levels of the ground state
of the caesium-133 atom. This definition refers to a cesium atom at rest
at a temperature of 0 K (absolute zero)."

Where Einstein comes in is that the cesium atom has to be at rest in
your reference frame.

> In that aliens galaxy existing far-far-away on a planet engaged in Star
> Wars, that cesium atom may not oscillate at that frequency at all!

Only in comic books and movies.

<snip rest>

Actually, I was so flabbergasted I failed to even give you a reason why
I would find holes immediately in your statement, to begin:

From http://en.wikipedia.org/wiki/Absolute_zero

"While scientists cannot fully achieve a state of ï¿½zeroï¿½ heat energy in
a substance, they have made great advancements in achieving temperatures
ever closer to absolute zero (where matter exhibits odd quantum

effects). In 1994, the NIST achieved a record cold temperature of 700 nK (billionths of a kelvin). In 2003, researchers at MIT eclipsed this with a new record of 450 pK (0.45 nK)."

Some "kooks" in the scientific community are even brazen enough to speculate that if we achieve such temps in matter, it will disappear! Well, return to the ether from which it was torn ...

> vertical adjustment (always in the back).

Yes, I've heard the tales of M. M. Muntz, but apparently so had the head designer at the audio mfr I worked at. They had a VCA circuit using a well known VCA chip. The data sheet notes mentioned a small value capacitor across two pins for stability. The designer discovered his circuit would work just as well without the cap and thus left it out of his design, so far out that there weren't even traces or pads to put the cap in should it become necessary (you can see where this is going, no?). The VCA vendor outsourced fabrication of the chip and all of a sudden the noise level of the VCA circuit would jump about 70 dB as the fader reached the bottom of travel, not desirable in an audio application. I spent a little time perusing the data sheets and our schematics, noticed the cap omission, soldered a cap across the pins of an offending circuit and within the hour we had the assemblers tack soldering caps we bought at a local electronics shop (not RS) onto assembled modules. The designer's comment was 'Well, it worked for quite a while...' Later we found customers with similar noise level jumps using pre-outsourced VCAs. Yes, they saved a few pennies on each module but lost about two dozen customers when they figured out what had been left out of their very expensive audio equipment.

When I started at that place I was told not to make suggestions
regarding modifications of existing designs lest I offend the managing
'engineer'.

On the other hand, someone has to take the project from the engineers
because if they don't, the engineers won't stop working on it.

From: Michael Coslo <mjc5@psu.edu>
Message-ID: <ep88o2$1fj2$1@f04n12.cac.psu.edu>
Source record: 46808

I'm putting together a homebrew mobile antenna based more or less on "20 dollar mobile antenna" that appeared in QST some years ago.

For those not familiar, the antenna consists of a tapped coil at the bottom, a spiral wound lower section, a tapped loading coil, and an upper stinger.

My question involves that spiral wound lower section. What would this be thought of? As antenna below the loading coil, as an inductor in addition to the other two, or some sort of hybrid of antenna/inductor?

How would this be modeled in EZNEC?

Apologies in advance if this was an incredibly stupid thing to ask! 8^)

What example?

Are you saying you don't believe that is the definition of the second
since 1967 or that you don't understand the definition?

Start with:

http://physics.nist.gov/cuu/Units/second.html

http://tycho.usno.navy.mil/cesium.html

I am saying:

Yes, I believe someone would search for "solid ground" to base measurements on. Again, yes, I believe that is about the best we can find in an un-perfect world ...

No, I don't think that is any better than basing it on my goldfish, and he/she is unpredictable (quantum effects perhaps.) But still, if all which availed itself to me were my goldfish--I'd be damn temped to start basing measurements on his/her activity!

At least your argument(s) cause one to think ...

Warmest regards,
JS

I don't suppose it ever occured to you that a practical hardware
implementation would correct for the actual temperature?

<snip nonsense>

Since you seem to like wikipedia:

http://en.wikipedia.org/wiki/Second

Hmmm, looks like they got their definition for the second the same
place I did.

Yes, there is a way. Look up "Cheap Yagis" with your search engine. You want WA5VJB's article published by the Clear Lake Amateur Radio Club in Texas. Great plans. His antennas use eight inch copper tube, but I've known people to make the antenna with welding rod, so substitutions are possible.

73 and good luck,

Bill Turner, W4WNT

I think that astronomers have made sufficient spectroscopic observations
and measurements to firmly establish that physical phenomina are
constant across the universe. Other dimensions may have different
measurements but they are constant in this one.

The "SECOND" is an arbitrary measurement of duration. It has been
defined with reference to specific measurements of a particular isotope
of CESIUM under specific conditions. That those specific conditions may
or may not be obtainable utilizing present technology is of no moment.
Adjustments to the best obtainable results are made all the time in
other areas. For instance the GRAM, the METER and the DEGREE. All these
units are defined and approximated in real life. The only place where
you can obtain absolutes is in conversion factors: 1 inch equals 2.54
centimeters, 1 degree Celsius (and it's derivatives: centigrade and
kelvin) equal 1.8 degrees Fahrenheit. The degree Fahrenheit is
determined by measuring the lowest temperature liquid water can reach
and the boiling point of the same water.
The upshot of all this is that everything in modern science is based on
these and many other values. They all seem to work. At least until you
get into quantum mechanics, which is another thread.

This reminds me of an old story about how you can become a hero in
Detroit. Save 1/2 cent each on 10 million washers. To become a bum in
Detroit, have those washers cause a 10 million car recall.

You might look into finding a way for that activity to occur
spontaneously as well.

Oh, you reveal you age. I worked on a bunch of those until I just started not letting them in the door. Seems a guy bought a bunch(100+) from a motel(s) that had gotten new TVs and had sold the for about $30 a piece. I think they had a 1 tube IF if I remember right. They wouldnt work at all in our area unles you had a really good antenna on a tall tower. The only places that had this was the shop I worked in and the local motels.

I think you’ll love this,

One thing I love about them, they don't keep log files of the news I read or files I download.
Take a look, I know you'll love it as much as I do.
They give you access to some of the best groups others may not carry.
You can find almost anything you are looking for.
Images, video, mp3 music, the real news from around the world... it's all inside waiting for you.
With some of the fastest connections around it's no wonder people love it and keep coming back.

Posting allowed!
Blazing fast downloads
2,000,000 new posts each day
800 GIGS of new multimedia content each day

Just go to http://www.newsdude.net and see why I love them so much. Byes!

Engineers design it and the techs actually make it work.

Mike

Let me suggest the ARRL publications CD. You get QST, QEX and NCD. I like them because I can then toss the paper QST copies, saving space, but better yet, you can print out the schematics, PCB layouts, etc, mark them up, cut them up, without guilt. The recent years are all PDF so you can sut the parts lists and paste them into a spreadsheet as you go collecting parts, pick out tables of interest and concentrate them into a reference binder, etc.

..

> Wars, that cesium atom may not oscillate at that frequency at all!

Through no fault of its own. Seconds may be a different
length in that far-far-away place. After all, the length
of a second is relative to velocity so cycles/second are
also relative, i.e. there is more than one way to accomplish
a red shift. 1. changing cycles divided by fixed seconds.
2. Fixed cycles divided by changing cycles. 3. changing
cycles divided by changing seconds.

Einstein also said, "God doesn't roll dice." One of the
quantum physicists responded, "Not only does God roll
dice, but he rolls them in the dark." :-)

What happens to its frequency of oscillation compared
to a stationary observer as it approaches the speed of
light?

The definition is relative, not absolute. If the
relative speed of the earth is changing, then the
length of a second is also changing and we would
have no way of knowing.

Hi Mike, I built one similar to this myself. I always assumed the spiral wound lower section added some distributed inductance that would reduce the amount needed for the upper loading coil. The inductance added by the spiral section could be modeled by adding a couple of inductive loads on the lower section. The effect of the loads will be to change the current distribution slightly on the lower section of the antenna. The spiral bottom does radiate.

The goal on this type of antenna is to adjust the center loading coil such that the antenna looks capacitive, and adjust the bottom loading coil to cancel Xc. Hopefully your impedance now looks like 50 ohms resistive. The spiral and center loading attempt to move the current distribution up the antenna so that more radiation occurs on the upper parts.

When I modeled mine, I only had a center inductive load, and the results were satisfactory. My goal in modeling was to design matching networks, I wasn't too concerned about current distribution. Also had a top hat, modeled as crossed wires. Later discarded top hat, not aerodynamic.

Homebrew mobile antennas IMO need center loading, no top hat, can accept power (loads up), and will stay attached to your vehicle at 80mph in a driving rainstorm.

go mobile. use a small antenna and an attenuator, maybe the one in the rig will be enough with just a 6" antenna or something like that. if it is indeed local to your shack it should be obvious when you get a few blocks away, then start hunting for rectifiers. it should also be obvious if it is from the transmitter as you drive around it. that might also find it if it happens to be from a 3rd party, like a bad ground wire on a power pole or something.

Also, do the test of shutting off everything at the breakers in the house... there is an outside chance, especially with the FM symptom and extreme width, that the AM station is getting picked up by some other device and modulating it... it could be getting into a TV and modulating the color burst, or a computer monitor, a old cordless phone, etc.

also check their fundamental and see if you can detect the fm on it, that should be obvious enough also and something you could go demonstrate to the engineer that may show him they have a problem that developed after their certification.

Not to worry. Any relativistic motion on our part will only effect
the clocks in the other reference frames. And we can't even
communicate with any of those people. :-)

625. FM Transmitter in a hot air balloon?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-24 23:23:58 UTC
From: Ron J <bigschlong@gmail.com>
Message-ID: <1169681038.776359.115700@l53g2000cwa.googlegroups.com>
Source record: 46638

So I was doing some reading and one article mentioned that a group mounted an FM transmitter on a hot air balloon. I was also researching on the methods used by the FCC to measured field strengths. So how does one go about measuring field strength levels if a company somewhere, somehow, sometime decides to mount their transmitter on a hot air balloon to avoid building a tower?

Would the FCC procedures still be valid? I wondering how the field strength tester would go mobile 30 meters from the radial or measurement point if the transmitter is changing position constantly.

The speed of the Earth relative to what?

But since the second is defined in the inertial frame of the Earth, it
doesn't matter.

Why do you think GPS satellites correct for their velocity and gravity
relative to the geoid?

BTW, you do know the second at sea level is different than the second
on top of a mountain due to gravity?

Well, since it wouldn't conform to any of the standard charts, they
would have to use a real field strength meter.

I am almost certain you posed that as a smart A$$ statement; however, I have considered that ...

What you just stated, the bible does indeed state, on a few different references (and NO, I DON'T know the bible scripture and verse--I am Catholic <grin> I drink AND smoke.) One such reference goes to making the point that all the names of the people to be "saved" are already listed in the book of life ...

I think of this, like this, our universe is nothing more than a "burnt cd", and we are just a translation of the data existing on that cd. Much like watching a movie on cd ... who knows, maybe God enjoys this movie ... just no accounting for taste.

Now I don't put a lot of probability in such--but hey, maybe you are right ...

Hi Mike,

Anything other than a straight conductor would add inductive loading, with less (if any) contribution to radiation. Close spacing of the inductor turns will add distributed capacitance. The closer to the feedpoint, the greater the I^2*R loss and the larger conductor should be, to keep the loss as low as possible. So, electrically, the best place for loading is at/toward the top end.

My mobile antenna setup consists of Hustler/Newtronics parts... but not quite out-of-the-box. For 20m, I use their RM15 (15m) loading coil + a 49" whip with about 6" cut off of it. The whip came from Larsen (pn W490). Though this effectively moves the loading coil toward the high-current end, it adds considerable radiating surface area. When the band was in, it was good enough to work the UK (using 100W) from my QTH near Seattle! I haven't (yet) tried an RM12 loading coil with an even longer W640 (64") whip. My setups for the other HF bands are similarly taller than the Hustler setup... the 75m antenna is quite tall! :-))

Because he's got a SINGLE frequency interfering with his station. To hell
with covering the entire band. A single parallel resonant network will do
something in the order of 80 dB of rejection if the L and C are at LEAST
something reasonable for Q.

Care to calculate the order of filter that will do 80 dB as a low pass
filter? And the Q of the components necessary to make the insertion loss
negligible at 160 meters?

Jim

Oh. Whatever was I thinking?

Then you accept 1.1111 Mhz may not be the same for "the aliens?" And, a cesium atom may NOT tell us anything about time at all? (just like the ruler tell us NOTHING about our size?)

Strange ...

At the very least, it's far easier to put in a single LC notch filter to
see what it does to the offending signal.

I was trying to think of things that could be done easily to determine
whether the problem is actually the transmitter or simply receiver overload.
One can easily assemble an LC circuit in the broadcast band with available
parts to try this out, while a high pass filter requires paying good
money for it and likely mail-ordering, or at the very least ordering
multiple coils to build up such a thing.

My first receiver was a cheap low end solid-state Hallicrafters in 1971,
and it overloaded terribly. I don't think anything could have been
done to fix it, but I know one time I took the parts list from the Handbook
for the high pass filter that was in there to solve the problem of AM
broadcast stations, and the parts store said they didn't have the
coils in stock, and they'd cost a pretty penny (certainly a pretty
penny for a 12 year old).

I had an upgrade (by professional electrician) about five years ago on my 35 y/o house. He upgraded the service level from 100A to 200A, added some outlets in the house and garage, etc ... stuff I've wanted since I moved in. The house was built with cold-water-pipe ground and it appears to be at least #8, maybe #6. The electrician said it could stay BUT he said code required an additional ground stake driven into the soil near the service entrance.

This is San Diego County CA. "Your mileage may vary."

One more thing, subject line "Yes, It's Really This Bad:" When I was a teenager, two families in the neighborhood went all-out at Christmas with the big outside lights. One guy said he kept blowing fuses (15A was the standard for all the branches in all the houses), so he "solved" the problem by substituting 25A fuses. Even as a snot-nosed kid I knew better.

An attenuator is the best and easiest test. Lots of ham receivers
actually have attenuators in the front end, so it may be just a
measurement thing. Basically if an in-band amateur signal is attenuated
significantly less than the spurs, then they are, indeed generated in the
receiver. The quick cure for that is to put a filter in the line to
remove the big signal on its own fundamental. Just make sure the filter
is either ONLY in the receive line or is capable of handling the output
power of the transmitter on any ham band.

Even then, there could be rectification in nearby clotheslines, fences,
etc., etc. I've cleaned up a couple of problems just by bonding a fence.

> And it may not even be the receiver. There could be something acting
> as a rectifier, that is picking up the transmiter signal and

> gutter, or a bad connection on an antenna, obviously something nearby.

Yep...usually that type is from a fairly nearby source.

Of course there are genuine spurs from broadcast stations. I remember once, we had a big wide-band FM signal on 2182khz. DOC (at that time the relevant authority) quickly tracked it down to a station running many KW about 12 miles from our receive site (and made them fix it--interference with hams is one thing, interference with a marine distress frequency totally another thing in their books).

I need to clear a grove of 100ft pine trees and it just ain't happenning. My sling shot is only making it to a height of about 70ft. Way short.

I've built a canon from sched 40 PVC with a 4" section reduced to a to 1" section which is about 4ft long. I'm using lighter fluid and a spark ignition. A 1" dowel weighted with 2oz of lead fits in the 2" PVC with a close fit. This still doesn't get over the grove of trees. It seems the lighter fluid just doesn't have enough power. Maybe I'm putting in too much or not enough fluid. How do you know if you have the right fuel air mix? I've heard that some use butane or propane in these.

Thanks
Bob Brunius

Please don't blame the messenger. If we could locate
an atomic clock at the center of gravity of the Big
Bang, we might have an absolute reference point -
(assuming that point is not moving. :-)

>> If the
>> relative speed of the earth is changing, then the

> with any of those people. :-)

But, Jim, that other reference frame may be yesterday
on Earth. A second today may be shorter than a second
was yesterday. I can prove that seconds are getting
shorter. It takes me many more seconds to run 100
yards than it once did.

I'm pretty sure that first second after the Big
Bang wasn't anywhere near the length of a second now.

Although "ground resistance" can be quantified and is, by the following
method:

Three stakes are driven into the ground at intervals. A measured current is
induced between the first and the last, while the voltage between the first
and the middle stakes is measured. By R=E/I, the ground resistance is
determined.

I last saw this done more than 10 years ago and I have no idea what the
numbers are. However, in poor soils, it must surely lead the installers to
drive more or deeper ground rods to meet the numerical requirments.

I hope this helps.

How long was a second before the Earth existed? Seems
to me that assuming the age of the universe can be
calculated in Earth seconds is just as bad as assuming
the Earth is the center of the universe. Similar
Earth-centric arguments can be made for both concepts.

> BTW, you do know the second at sea level is different than the second

So how is it possible to calculate the age of the
universe in Earth seconds? Are we talking sea level
seconds or what? Are Black Holes the same age as the
universe?

He's right. I made my first FD contacts on 2M using a TV-twinlead J-pole in a length of PVC pipe. Worked one contact over 100 miles with my 5 watt Yaesu FT-530 very near ground level. (Yes, the other end had a beam.)

The TV-twinlead J-pole is a bit tricky to build. I much prefer using copper water pipe, but I made one of twinlead since that first FD. Twinlead's big advantage: it rolls up and fits in your pocket, as there is no ground plane. With a simple plastic loop at the top, it can be hoisted aloft with kite string or hung by a stray nail on Uncle Hank's porch roof, etc. Rigid, permanent mounting is always optional but never required.

Plus, it gets them ol' RFs away from yor haid.

671. radioshack UHF corner reflector outdoor antenna feed point impedance

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-25 05:07:07 UTC
From: CCW N4AOX <wynn9701@bellsouth.net>
Message-ID: <HVWth.15567$uW.9135@bignews3.bellsouth.net>
Source record: 46585

I thought about using one of these for DTV reception. I am curious about the feed point impedance. The antenna (see it at radioshack.com) looks like a corner reflector of sorts. But, it has an extended boom ahead of the feed point dipole with yagi like elements (cut much shorter than the dipole). The feed point is an approx. 1/2 wave split dipole, insulated and center fed.

The feed point 1/2 wave dipole (center fed) would have a 75 ohm impedance free space. Corner reflector design data shows an approx. 70 ohm impedance for a similar configuration, but without the extended boom ahead of the feed dipole.

The RadioShack accompaning literature implies a 200-300 ohm feed point impedance, ie. it states that a 300 / 75 ohm balun and RG-6 feed line should be attached. Has anyone measured, or modeled the feed point impedance of this antenna or have an explanation of how they arrive at 200-300 ohms?

The Collins AN/URC-32 was being taught at that same time, the early spring of 1963. I distinctly recall getting a just-barely-passing grade in that beauty because it was the last class in the school. I had my orders and I was all studied-out after 38 weeks.

Each SRT-14/15 had its own bank of bulbs -- six or eight in a wire cage. No idea of the series/parallel connection, though. The -14 did 100 watts. By adding the HPA and its PS, the set became a -15 and did 500 watts.

Never performed the shorting bar trick myself but I saw the aftermath of one of my crew doing it (AN/ULQ-6 - sometime in 1977). He converted much of the line filter to a puddle of slag.

Jim:

One last try, then I give up. It is much worse than that, as you are all ready assuming that time exists. Most of us fall error to this. It certainly seems to exist because how else would we get to our appointments on "time."

What we do is confuse time with movement. Certainly you can see that our earth time is based solely on movement, the spinning of the earth. Indeed, we cannot "measure time" if we don't see something moving. Even your watch depends on movement, either the watch spring driving spinning gears, or the movement of electrons in its tiny oscillator.

Take away movement and you take away our time ...

But, there could be a "real time." A time which does not depend upon movement. Indeed, there is good indication that it may exist. As, the big bang would have needed time to have happened in (or, something akin to it.) Otherwise, the big bang IS time and time is only movement. I know, at first it appears rather a circular argument--takes a bit of getting used to.

Just think about it from "time to time" (or, as you are moving about <grin>) ... no reply is necessary.

He reported a single frequency, that does not limit the problem to a
single frequency. I already explained that.

>Care to calculate the order of filter that will do 80 dB as a low pass
>filter?

That is not particularly difficult, quite common in fact. Standard
engineering syllabus teaches us that you enjoy a 6dB/Octave or
10dB/Decade roll-off for each reactive element in a filter. I already
suggested a 6 or 8 pole filter which brings us up to your 80dB for an
entire band, much less a single frequency. Slam dunk simple.

I am quite sure that many here that are experienced in actual bench
work would nod in agreement that the better part of a project is
building the things around the electronics - like an enclosure,
connectors and such - than with the electronics. 8 off the shelf
items (actually 4 pairs) vs. 2 with one of the two needing to be
variable AND tuned? Is that such a major demand on the bench skills
of an amateur radio operator?

>And the Q of the components necessary to make the insertion loss
>negligible at 160 meters?

For receive? C'mon now. And 160M instead of the band he is
interested in, 80M? Anyone can contrive to fail, that's plug simple.
The next set of restrictions will have us going down the garden path
to build a crystal lattice filter for the sake of unneeded
astronomical Q and to achieve spectacularly low insertion loss - turn
up the RF gain.

The issue is moot with the probability the issue revolves around spurs
from corroded, weather beat connections. I have a buddy who suffered
identical issues from an AM station 1 mile away. He wire brushed poor
joints and solved the problem that filters couldn't solve.

<jimmiedee@bellsouth.net> wrote:

>Oh, you reveal you age.

Hi Jimmie,

I did my apprentice work in TV as a teen in the mid 60s. The real challenge came when I was in the Navy (1970) and we put out a call to the Bay area for folks to donate their TVs for charity (Xmas of 1970), and the ET school would fix them for free for redistribution to the needy.

My crew took in 100-150 TVs and 200 radios and turned out 60 or 70 TVs and nearly all the radios. Some TVs were so old as to have vertically mounted tubes with a mirror to view them. I taught the fellows how to cannibalize the truly dead to resurrect the lame. This was the gift of a Navy technical education. At sea, there was no mall to pull into and go to Radio Shack - you had to make the broken stuff work or the Captain would keel haul you. This demanded every tech know electronics, not board swapping. I never had such an enthusiastic class. These guys learned like sponges, and tackled every problem like a commando gutting a commie.

One interesting incident came when a student asked me for a set of rabbit ears to test his work on a tough-dog TV. My budget was like $20 a week from the Old Man's wallet (and I wasn't going to ask him for that). I told the student that we had a ground bus-bar that ran the length around the repair shed (a former laundry) that would work just as well as it was many wavelengths longs so as to not short the signal (sitting in the middle of SF bay offered huge amounts of available RF).

He connected an alligator clip lead to the antenna input, the other to the bus bar; the lead turned to smoke, the insulation dripped right off like a length of spaghetti, and then fused open.

The astonished crew quickly learned the hazards of poorly engineered grounds in commercial equipment, the hazards of using a service cord to defeat an interlock, and why we in the trade called it a suicide adapter.

What, a poor example? GIGO.

>If the darn cesium atom won't vibrate consistently at the same freq, you
>are asking me to base beliefs on it? <look-of-shock-and-awe!>

Your belief system makes an unwarranted presumption - THAT is the
basis of poor belief, not the atom's resonance.

>If something as simple as a high power pin-point laser can affect it ...

Another presumption. Perhaps true, useful, but it doesn't invalidate
the simple mechanics. Failure is easy to achieve - it is celebrated
in a speech before Congress every year.

The Cadillac of HF.

Hi OM,

I was teaching at TI 7 years later. By then we had both added and
retired the TED/RED (VHF/UHF) with the SRC-20-21, added the URC-17c
(RTTY), and topped it off with a "systems" class (for teaching patch
panels, tuners, and encryption) to lengthen out the curriculum. That
was called A4, you probable stopped at A3 (Radar had A5 and A6
sections that I schooled in before becoming an instructor in the Comm
division). The system lab was two identical ship's comm stations
HF/VHF/UHF in all modes. One side held a comm with the other through
dummy load leakage.

I've got one of those things. I use it for ATV. I consider it a 300 ohm
feed.
I've never tried to measure or model it, but I'm just trusting the
designers
considered that, being it's semi critical for UHF. Also, the antenna is

quite broadbanded, being a psuedo log periodic of sorts. I imagine the
feed impedance can change a bit with frequency. I doubt it's the exact
same at
600 mhz, as at 420 mhz.
BTW, using all 300 ohm line is less lossy than using the coax and
balun.
Well, unless maybe you use some super duper coax... At 420 mhz, I
always
had better results with the 300 ohm line. The only drawback is a good
bit of loss when it's raining hard.. :/

Basically the same as my "plastic bugcatchers" I make out of old CB and
ham
fiberglass antennas. The spiral just adds a bit more inductance. How
tight, and
how many turns would determine the overall loading. IE: just a few
spiral turns
won't do much for 80m. Your bigger lumped coil is going to be doing
most of
the dirty work. The spiral will just add a bit. But on the higher bands
like 10m,
that spiral could have quite a bit of effect on tuning.
Myself, I don't use the lower spiral section. Those smaller coil turns
are more
lossy than using the bigger lumped coil. It's really best to just use a
straight
lower section, and have all the loading at the center lumped coil.
That coil is higher Q, and more efficient. You don't want to degrade
things
by using the lower Q lower spiral windings, when you have a big coil
above
those.
My present best antenna is a 6 ft 20 meter hamstick that I butchered
up.
I did away with all the thin coil windings, but kept enough wire so I
could have a
fairly straight section at the bottom. I'll wrap maybe a turn or two

just to keep
it in place better, but I don't consider it part of the coil. I wanted
max performance.
So..Instead of placing the coil at the center of the fiberglass whip, I
mounted it
nearly at the top. The top one foot of the six foot whip is where the
coil is.
Then I have a 5 ft stinger whip attached to the top of the glass whip.
That makes it a true center fed, with 5 ft under and above the coil.
The tapped coil at the bottom is the matching device. That can vary to
the
install.. The higher you can mount the loading coil, the better,
unless
maybe the stinger is too short. I don't have that problem with a 5 ft
stinger.
The antenna is a stout talker. Even on 80m. And didn't cost me a cent.
All was
junk I aquired... BTW, for added effect, I often extend the base below
the
coil with a 3 ft hustler mast. In that case, I have 8 ft below the
coil, and
5 above. In that "parked" mode, it really kicks butt. Mine tunes 80-17
with the 5 ft stinger. On 15-12-10, I use shorter fixed length stingers
to tune, with
the coil bypassed. Naturally, the usual low band 11 ft antenna is a bit
tall for the
highest bands.. :/. I actually don't work the higher bands much. I'm on
40 in the
day, 80 at night most all the time. But I can work all the others if I
want to.

i used a "surf rod", a fishing rod built for fishing from the beach, big and strong. i tied about 4-5 old wheelnuts (or anything heavy), worked really good. make sure the spool is full of fishing line first, and that its strong line. and you may snap the line trying so you want to start small and build up the weight.

This is presuming there is nothing/no one nearby that can be damaged/injured.

Good luck.

In the past (1961) I have used a bow and arrow (borrowed from an archery
enthusiast), and also a rocket (fireworks type) launched 'mortar style'
from a cardboard tube. Both pulled up linen thread (carefully coiled up
on the ground), which I then used to pull up nylon twine, then thicker
nylon etc.

Damm! I dumped a few years worth, when I bought the ARRL CD. Now I keep up by buying the annual CD from ARRL, in each Feb, or thereabouts. It has QEX, QST and NCJ on it.

The CQ one is also pretty good, even although it has some articles withheld because of copyright arguments, mainly fractal antennas.

688. Resonating and Matching To A 476 MHz Yagi Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-25 11:12:29 UTC
From: ian_chappel@hotmail.com
Message-ID: <1169723549.705334.102080@s48g2000cws.googlegroups.com>
Source record: 46602

Hi,
Without purchasing expensive equipment I have a UHF hand held transciever and I have disconnected the flexible < 1/4 wave antenna and connected some coax (this assumes the output impedence of the handheld into the flexible antena was 50-70 ohms). I have designed and built a 10 element Yagi.

To optimise the matching to the driven element I used a gamma match, the reality is I don't know if the driven element is at resonant frequency let alone correctly adjusting the gamma match.

I was just reading another posting on rec.radio.amateur.antenna, where the author suggested using 300 ohm TV ribbon as it is less lossy than a lot of coax at UHF (476 MHz). Is this true? 300 ohm ribbon will remove the need for a gamma match at the antenna end, but at the transmitter end an unbalanced to balanced (50 to 300 ohm) balun will be required. Would a normal TV set balun suffice for 0.5 watt of transmit power?

To resonate the driven element I have contemplated using a UHF Gate Dip Oscillator (GDO), has anyone succeed in doing this with minimal test equipment such as a GDO? If the folded driven element resonates at 476 MHz I will accept that it's impedence is 300 ohms.

All this may seem very disjoint but it is why this hobby has never ceased to fascinate me.

Thanks in advance for any useful suggestions.
Ian

Based on my last experience, I suggest that you borrow a compound hunting
cross bow
and no-point fishing arrows (they are substantially heavier) with at least a
50 lb pull.
Use a fishing reel with fishing line that is light but strong. If the line
is too light it will
probably break. Use the fishing line to pull over twine or something heavier
and
then a multicore Dacron rope. Allow for enough line to go over the "grove"
by about 3 times

I use the end ropes to support pulleys and lines through the pulleys to
support the
antennas. One pulley rope is tied off. The other has 5 8-gallon containers
of
anti-freeze that serve as the balancing counterweight for the 220 foot
antenna
of #10 copperweld that is centerfed with 600 ohm ladder line.

Hi Ian

Sounds like you are having fun!

- I would suggest that using a GDO for meaningful antenna work at UHF would incur quite a few inaccuracies. The big problem is how to couple it to the element itself without detuning it by its presence. You will hear some howls of protest but I personally wouldn't bother to try making it a resonant length. It's really not that important for radiation efficiency. The gamma match introduces a huge reactance that also has to be allowed for.

- Using Ocarc's loss calculator 300r ribbon runs about 2.5dB for 100ft/30m. 450r open window ribbon runs about 0.7dB for the same distance! (http://www.ocarc.ca/coax.htm) RG213 (approx 1/2") coax is around 5dB. Keep in mind that ribbon bends and proximity to objects will cause problems that coax wont.

- Converting coax to a balanced feed at the antenna can be very easily done with a 4:1 coax balun. This is basically a extra loop of 1/2 wave length coax built like http://www.n-lemma.com/calcs/dipole/balun.htm You will still need to match at the antenna in some way. Maybe replace the gamma with a hairpin, use a delta match or maybe increase the number of driven elements folded dipole style to get the Z up to 200 ohms. A yagi feedpoint Z is going to be maybe 10-20r. One extra driven element (simple folded dipole) will multiply that by 4 and a third element another 4 times. That will be close enough to 200 ohms to work fine. You can also play with the extra element diameters to vary the final feed Z.

- I personally wouldnt use a UHF TV balun without testing first. The problem is quality of manufacture!

Hope you find this useful. Only some of my ideas!

Cheers Bob W5/VK2YQA

Seems like an argumentum ad populum. If we lived
near a black hole, our seconds could be 10^6 times
longer than they are now. What would most people
think then?

Using a relative time standard that obeys the rules
of relativity to assert the absolute age of the
universe seems really strange to me.

The point is that our "standard" second changes
with velocity and we have no idea what our
velocity is or was or will be. We are defining
our average velocity as a constant without any
evidence whatsoever to support that definition.
That's no different from defining our average
position as the center of the universe.

Wire clamps on the ends of the driven element that allow you to adjust
the length of the D-E for minimum SWR. See Fig. 1 and page 2, bottom of
column one.

here are two links for you to get you on the air fast
and 'on the cheap' ! (but are not Yagi design)

both of these can use copper wire you may already have,
or find in the recycle or trash pile.

half square for 2m (not a yagi but fast and cheap to build direct fed no
match)

http://www.cebik.com/vhf/hs.html

Moxon for 2m (again, not the yagi)

http://www.cebik.com/moxon/moxbld.html

similar gain as a 2 element yagi but takes up less space
and it is direct coax fed so no matching needed !

good luck with the project !

james (also used when making reservations)

hi joe

this will fit in a suitcase if you use stranded copper #14 thhn
wire to build it. use sched 20 pvc (don't solvent weld it) so you
can just slip it together for use with short coax to the ht.

the half square for 2m nice gain but it is directional.

http://www.cebik.com/vhf/hs.html

Your in the right area, but you might want to use a POTATO CANON - like the fisherman due at the beach to get the line out a couple hundred yards.

They use a metal pipe or heavy duty plastic pipe, with 1 end buried in the sand and a small pinhole to light it off (for safety, you could use some kind of fuse in the hole)..

Most of them use hairspray and a piece of POTATO with the hook embedded in it.. abt 4-5 squirts of the hairspray and the potato.

My $00.02

Sounds like my antenna, if the current price is 24.99. It is 300 Ohm output.
It's called a Corner Reflector Yagy. I would'n get too exited about the
impedance, but you can get some idea about the gain by going to
http://www.hdtvprimer.com/ANTENNAS/comparing.htmlI
Scroll down to the Radio Shck VU75, and look at the UHF gain. Keep in mind
this is an old design consumer product, and probably predates any computer
simulations. More than likely (hopefully) the 300 Ohms means it works better
feeding a 300 Ohm load than a 75 Ohm load. In general, when you add
directors to a dipole the impedance goes down from 75 Ohms, not up. They may
have gotten the impedance up because the feed point is several inches from
the center of the driven element.

I am using it with a 300:75 Ohm transformer at the feed point, feeding a
Channel Master UHF only ptreamp, mounted just below the rotator. Feed line
is about 50 feet of RG6. On good days I get HD stations from 65 miles away.
Antenna is at about 25 feet.

The point is that you have to compare clocks in different reference frames to know it. The second remains the same in each frame of reference. Since everything we perceive is perceived with respect to our own reference frame, we really need only concern ourselves with our own reference frame. But you can still worry about the other ones if you really want to. ;-)

Since that would change the defined conditions for the unit of time,
the number would probably change.

But, since we couldn't live that close to a black hole, the point is
moot.

If we lived on Mars, the unit of time would be different too because
the defined conditions for the standard would have changed.

So if we ever colonize Mars, how do we keep Earth and Mars clocks
in sync?

Simple, we define a set of standard conditions that applies to every
place. Any place that doesn't have those standard conditions gets
a correction, just like GPS satellites do.

The second becomes whatever it is defined to be.

> Using a relative time standard that obeys the rules
> of relativity to assert the absolute age of the
> universe seems really strange to me.

Your're playing semantic games Cecil.

All measurments of everything are relative to some standard which is
pretty arbitrary and doesn't matter as long as everyone uses the
same standard.

The standard for time for human beings is based on a particular
property of cesium on a defined Earth.

Using that standard, the age of the universe is what it is.

Use a different standard, you get a different answer.

So what?

Since there is no such thing as an absolute frame of reference or
absolute velocity, your point is meaningless.

Time is defined with a velocity of zero relative to the Earth, not
Mars, the Crab Nebula, nor the center of the universe.

The standard is a measurement standard, not some revelation into the
meaning of life and everything.

I didn't bother to read the ad, but if it can be calibrated to NIST
standards, yes.

You can also do it with a spectrum analyzer and a calibrated antenna.

Jim:

No one can dispute your, "If it ain't broke, don't fix it!" argument.

Anyone would be fool to throw away our present theories, equations, etc.

However, your argument of, "I am only worried about what happens in my backyard" would halt progress and advancement towards the real and correct understanding of these things.

But hey, if what we have right now is working, "Use it!" is my motto ...

Warmest regards,
JS

Jim:

No man is an island, and no cesium atom is an island either.

The spinning of this earth is directly related to the vibration of the cesium atom.

The exact same laws of math and physics which control the vibrating of that cesium atom control the spinning of this earth.

Sheer logic is all which is necessary to know that ...

Warmest regards,
JS

Bob,
When I was a kid I had a "Big Bang" cannon that used powdered carbide and
water. It used about 1/10 a teaspoon of carbide and about a half a cup of
water as soon as it quit fizzing you ignited it with a flint striker.

That was the same argument used by Catholic Church
when they put Galileo under house arrest for the rest
of his life. Galileo talked about space. We are
talking about space-time - not much difference.

> --
> Jim Pennino

I think my school will lend me a spectrum analyzer, but not sure if I can get access to a calibrated antenna. One of my school projects involves in measuring the field strength of a low power FM transmitter mounted in a "smart" flyer. Really the flyer is just a toy helicopter fitted with sensors and given a "brain" by the computer science folks. The idea behind it is that it's suppose to monitor local traffic conditions using a video feed and then it will broadcast some pre-recorded messages via the FM transmitter warning on-coming drivers of potential road blocks.

However, the drivers will need to tune their radio station to a specified frequency. I'm not involved with the frequency stuff, so I don't know how it's going to play out with the feds.

Anyway, I'm supposed to determine the range of the FM transmitter by measuring the field strength. But I'm reading some propagation text like Les Barclay's Propogation of Radio Waves and found out that field strength varies with antenna height, distance from receiver and transmitter, and also the landscape. I've also scoped out some FCC procedures for measuring radio broadcast, and they have some 50,50 curves that I don't understand too much. But the FCC assumes that the transmitter is fixed. In this thing, the transmitter is moving around, so I'm having a difficult time figuring out how to come up with some transmission range diagram.

The intent of my original question is to find out how someone would measure it. I'm sure the balloon folks had the same issue.

Richard:

That is the worst statement I have EVER heard you make.

Time is a MAJOR factor in antenna calculations.

If you wish to decide what is on topic and NOT on topic, how about corrosion limiters? Nylon rope? (yes, used by some as guys!) Ground conduction enhancers? (salts) Trees? (yes, used by some as masts) The antenna as art? (yes, some have to please their neighbors) Trenching equipment? (yes, some go overboard on the ground establishing wires) Bumper jacks? (yes, some use these to hoist up their collapsible masts) Etc., etc.

Your interests about antennas like in a purely physical realm using established methods, both practical and computational--some of ours don't. Why your interests should over-ride others is a bit perplexing to me ...

Regards,
JS

ALL units of measurement are arbitrary. Once a standard is set, that's
(if you are sane) what you use.

By that convoluted logic:

The dollar is an arbitrary unit so why strive for accuracy in your paycheck?

The inch is an arbitrary unit so why should the carpenter strive for
accuracy in matching the new door to your old door frame?

Miles per hour are based on two arbitrary units so why should the cop
give you a ticket for doing 90 in a 35 MPH zone?

The liter is an arbitrary unit so why should the maker strive to ensure
there is 2 liters of soda in a 2 liter bottle?

But, I know you are just playing word games here.

Sir:

You SERIOUSLY miss the point.

All you named there are an invention of man and man allows himself to be
governed by them ... (some don't, ever hear about income tax evasion and
prisons?)

The laws of mathematics, physics and the sciences exist in an absolute
form, somewhere ...

Warmest regards,
JS

"Real" calibrated antennas that meet FCC requirements with calibration
traceable to NIST aren't cheap.

Though if all you are doing is trying to estimate range and don't
have to send traceable data to the FCC, you could get a good idea
by using antenna modeling software and modeling the antenna in free
space.

736. MI5 Persecution: Toronto Freenet supports free speech (376)

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-25 19:38:35 UTC
From: MI5Victim@mi5.gov.uk
Message-ID: <m07002520325729@4ax.com>
Source record: 46552
Cross-posted to:
it.discussioni.geometri,it.comp.giochi,rec.radio.amateur.antenna,hr.rec.glazba.snimanje,alt.consciousness.4th-way

Despite an orchestrated campaign of attempted censorship by UK-resident newsgroup readers, TFN did not bow
to demands for a suppression of freedom of speech. TFN general policy on the matter is as follows;

Draft Policy on Account Deactivations due to News Group Postings
==========

News group postings occasionally take the form of a message which goes against the "topic" of the conference.
For example, a derogatory message about Canadians in the soc.culture.canada.

Members of such news groups then may send a message to the system administrators asking that a user's account
be terminated because of such posting.

The Toronto Free-Net Board of Directors has taken the position that the only postings that will get a person's
account terminated is material that is illegal under Canadian law. Otherwise, the Toronto Free-Net will not
take any action.

Freenet Executive Director Mike Anderson had this to say regarding the continued attempts of a minority of usenet
participants to have my account on his system deactivated;

The TFN's policy is not to take action against members unless they contravene the Criminal Code of Canada, or
engage in practices such as forgery, attacks against other computer systems or mailbombing.

Mr. Corley, while possibly being very annoying, has not contravened the TFN's policies. The TFN believes strongly
in freedom of expression, while recognizing that the price for such freedom may be a high signal-to-noise ratio in Usenet.

If Mr. Corley breaks the law, we will take action -- until then, he has the same rights as any TFN member to post
to Usenet newsgroups. Actions such as mailbombing the TFN in protest will be met by strong complaints to the
originating site's postmaster. The best defense against unwanted postings may be simply be to ignore them and deny
the poster an audience.

TFN Executive Director Toronto, Ont CANADA

Personally, I find it gratifying that my contributions to usenet discussion are recognized as being conducive
to a high signal-to-noise ratio by their quality and thoughtfulness.

I should have mentioned that there are/were two versions of that antenna. The one I was talking about is 40 inches long. The other one, which I think is no longer available, is more than twice as long, and equal to the UHF portion of the VU 120 or VU190 (count the elements). The picture in the catalog of the short one is wrong.

Subject: BBC's Hidden Shame

Remember the two-way televisions in George Orwell's 1984?
The ones which watched you back? Which you could never get
rid of, only the sound could be turned down?

Well the country which brought Orwell into the world has
made his nightmare follow into the world after him.
Since 1990 the British have been waging war against one of
their own citizens using surveillance to invade privacy
and a campaign of abuse in the transmitted media in
their efforts to humiliate their "victim".

And the most remarkable thing about it is that what they
do is not even illegal - the UK has no laws to protect
the privacy of its citizens, nor does it proscribe
harassment or abuse except in the case of racial abuse.

A lot of people in England know this to be going on,
yet so far they have maintained perfect "omerta";
not a sound, not a squeak has escaped into the English
press, and for all the covert harassment absolutely
nothing has come out into the public domain.

Have the British gone mad? I think we should be told.

From: "Mr.B" <dgb01@stir.ac.uk>
Newsgroups: alt.conspiracy
Subject: Re: BBC's Hidden Shame
Date: Mon May 8 05:32:13 1995

Mmmm.

Who, exactly is this victim you're talking about?

First up, Britain or the UK (not 'England' - England is
a part of Britain, like Kansas is a part of the USA) does
have laws that protect the individual from harassement -
you can't just threaten people willy nilly. There are laws
against that. And if someone lies about you in the press
or tv then you have recourse to libel/slander etc. laws.

True, Britain has no 'privacy' laws as such, but isn't that
a good thing? As of this moment, the govt. are considering
a privacy law, but it is unlikely to succeed. Why? Because any
such law would benefit the priviledged and those in power.
Privacy laws, while supposedly protecting the individual, help
those in power hide their mistakes/scandals. They stop the press
etc. investigating. Privacy laws are undemocratic - they prevent
the people from keeping an eye on govt.

And stop looking for some kinda conspiracy in the British
press. It's hardly perfect, but your notion that they don't
cover/campaign against press legislation, harrassment,
discrimination, human rights etc. is plain wrong. You've never
seen a British paper in yr life.

You clearly have a specific case/individual in mind. Speak up!
The thought police aren't coming round just yet.

Douglas.

Subject: Re: BBC's Hidden Shame

Confession time - the victim is/was me (except my name isn't
Corley, but that's irrelevant). What happened was not threats;
just invasion of privacy, in a partiicularly flagrant and
shocking way, in a way which most people would consider to
constitute harassment.

You know there's a particular category of person with mental
illness to whom TV and radio "talk", ie they feel the broadcast
is directed at them in particular? This happpened to me,
quite some time ago in the UK (I'm originally from London,
so I've seen plenty of British media print and other).
They invaded my home with their bugs, they repeated what I
was saying in the privacy of my home, and they laughed that it
was "so funny", that I was impotent and could not even communicate
what was going on. Who did this? Our friends on BBC television,
our friends in ITN, last but not least our friends in Capital
Radio in London and on Radio 1.

How did they do this? I'll give you an example. About a year ago,
I was listening to Chris Tarrant (Capital Radio DJ among other
pursuits) on his radio morning show, when he said, talking about
someone he didn't identify, "you know this bloke? he says we're
trying to kill him. We should be done for attempted manslaughter"
which mirrored something I had said a day or two before
(I'm not paranoid, honest!). Now that got broadcast to the whole
of London - if any recordings are kept of the shows then it'll be
there.

You mean the category where they think that everyone is after them ? that
one ? So lets get this straight you know you are paranoid and you think
that they are out to get you ? Uh huh, try putting the two together and
see what you come up with.

>quite some time ago in the UK (I'm originally from London
>so I've seen plenty of British media print and other).

>Radio in London and on Radio 1.

Oh yeah, I can see it now. All of them banding together, in a united effort against one man. So ITN, the BBC, and Capital all decide to sit round the table and they come up with idea of breaking into someones house, putting bugs everywhere, listening in to his conversation, and shoving it out on the news everyday. This someone has nothing to do with politics, or business, or entertainment, just an ordinary Joe Bloggs who seems to be extremely paranoid.

Have some sense, grow up and smell reality. What you are talking about would take loads of planning, tens of thousands of pounds and lots of people involved in the planning, execution and maintenance of it. You must have a very high opinion of yourself to think you are worth it.

>How did they do this? I'll give you an example. About a year ago,
>I was listening to Chris Tarrant (Capital Radio DJ among other

Of course you are not paranoid, just slightly mad. Did you ever look for the bugs in your house ? If not, why not ? I mean if I thought that was happening to me, I'd search the place from top to bottom, I mean I live there I would know if anything was out of place. If I was really paranoid, whoops I mean suspicious, I would call in one of those bug detection teams which have those machines that pick up the transmitted radio waves. This reminds me of BUGS, that new programme on BBC1 on saturdays which is all about this kind of stuff, but, shown as a drama / thriller. I suppose thats based on you as well is it ?

>is that there is a conspiracy in Britain, that it encompasses the
>broadcast media, and there is no way of breaking the conspiracy.
>The people who are involved in it will not open up.

What a load of jolly hollyhocks, I would say something else but, apparently students are not allowed to swear on newsgroups in case it damages the reputation of the university or some such jolly hollyhocks.

This guy is extremely paranoid to suggest that the entire British media is after him in such a big way. He gives no real reason as to why they are after him, just that he suffers/suffered from a slight mental

disorder, could it be paranoia perhaps ?? No surely not.

I put it to the house that he has never recovered from this mental disorder, lets come out with it and call it paranoia, and thinks everyone is after him. Remember just because you aren't paranoid, doesn't mean they aren't after you.

This guy has a serious problem to suggest that the media would go to such lengths just to single out and ridicule one person. I mean apart from anything else, we (the listening masses) wouldn't be interested unless it concerned the royal family, politicians or showbiz personalities. e.g. the camillagate tapes. I would think that almost everyone, no matter how much they went on about infringements of privacy read the transcripts with interest. I really don't think that Joe Bloggs ordinary guy or paranoid nutter would have the same appeal. Well actually I dunno. :)

Regards,

Paul.

742. Strongest signals received via skip?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-25 20:30:58 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1169757058.727360.319810@a34g2000cwb.googlegroups.com>
Source record: 46551

We expect the local down the block may overload our receiver when he keys up his kilowatt 40kHz from the frequency we're listening to, but what are the largest signals received via skip in the HF bands? What are the chances you'd ever see anything as large, say, as 0dBm into your receiver via skip? (0dBm = 73dB above s9, given that s9 = 50uV into 50 ohms.) This could potentially include SW broadcast stations running fairly high power.

Cheers,
Tom

<assemblywizard@gmail.com> wrote:

>That is the worst statement I have EVER heard you make.

You actually HEARD it? Therein might lie your problem.

>Time is a MAJOR factor in antenna calculations.

Of course, when I first used ELNEC, it took forever to model some
designs that takes EZNEC forever now (infinities being relative and
all). Some of these time dialogues underway now exhibit Zeno's
web-enhanced paradox: No one gives a shit before you are halfway
through the thread. I only look at every third post at most; so for
me, dialog has simultaneously jumped into the future while becoming
retrograde (moving backward in quality - time is money).

The upshot is that I get to hi-grade the nonsense, and peel the
banality one layer at a time for its comic content:

>If you wish to decide what is on topic and NOT on topic, how about
>corrosion limiters?

Been there.

>Nylon rope? (yes, used by some as guys!)

Been there.

>Ground conduction enhancers? (salts)

Been there.

>Trees? (yes, used by some as masts)

Been there.

>The antenna as art? (yes, some have to please their neighbors)

Been there.

>Trenching equipment? (yes, some go overboard on the ground establishing wires)

Been there.

>Bumper jacks? (yes, some use these to hoist up their collapsible masts)
>Etc., etc.

Well, I haven't touched on that perhaps, but the list is hardly
exhaustive - is it?

>Your interests about antennas like in a purely physical realm using
>established methods, both practical and computational--some of ours
>don't.

This would make more sense with a predicate... then again, maybe not.

>Why your interests should over-ride others is a bit perplexing
>to me ...

Then you should invest some time in the archives given the number of hits on topics you consider to be foreign to me having "talked" about. Your list reveals very little reading on your part. That is in scope, not currency (I've been here some 12 or 11 years now). As already offered (you didn't hear that either?), yours is a cultural problem, not a technical one.

Now, seriously, you don't REALLY think that I would limit my correspondence to just ONE topic - do you?

That is what happens in big cities. Hell, it scared me to death when I first
started working in Manchester. People keep talking to me on the streets,
even if its just to say hello, and I've no idea who they are. This happens
to most people, don't worry about it.

>>paranoid, whoops I mean suspicious, I would call in one of those bug

Doesn't this suggest to you that there are, in fact, no bugs to be found?

>Over Easter I went to the police in London, telling them basically
>what I've posted here. I don't think you'll be surprised to learn
>that I didn't get very far; they asked "why would they be doing this to
>you in particular?" and the answer "they are because they are" doesn't
>go very far.

Exactly. All you have offered so far as proof of your harrassment by these
people is:

1) Someone on radio said something that you had recently said
and
2) People on the streets seem to recognise you.

These are both perfectly normal occurences and happen to lots of people every
day so it is unsurprising that people here, and the police, are not taking
you seriously.

Trying to always keep an open mind about things I would say that one of three
things is likely.

Either there is a lot more to this that you are not telling us, or you are
messing about or you have some genuine delusions. I'd like to think that in
two of the three cases you would find some real support here, but it seems
unlikely I'm afraid.

>even if its just to say hello, and I've no idea who they are. This happens
>to most people, don't worry about it.

The key is the pattern, or a change in the pattern. I've lived in London
almost all my life, and just walking around the streets, I never got
hassled by anybody. All of a sudden, people start harassing you,
throwing abuse at you, behaving as if they know you personally, as
if they've seen you before somewhere. I read in the papers that this
happens to Colin Stagg and people like that Eastenders actress, but
they've had their picture in the paperes, so that is understandable.
In a couple of cases people have even known my name - when I was in
London over Easter I was walking down Shaftesbury avenue in the
West End when somebody (no idea who they were, just some bloke with
his girlfriend) called me by name - quite clearly, and my name is
distinctive. This also happened once about four 1/2 years ago, onn
the tube - some blokes I had never seen started chanting my name
and a term of abuse.

It's the pattern which convinces me there's something to it - and
would convince any impartial abserver who could see things tyhrough
my eyes.

>Doesn't this suggest to you that there are, in fact, no bugs to be found?

There's a little story behjjind this. First iof all, in 1992 I worked
for a company where the people made clear they knew what was going on,
first of all directly (the very first evening I was there I went out to
the pub with them and the Technical Directpor said to another guy,
"is this the bloke who's been on TV?" "yeah, I think so") and also
indirectly, by rep[peating stuff I was saying at home in London and
in my rented accomodation there (I moved several times in the course of
1992 and they followed me each time). Now, if "they" (the buggers)

knew their bugs could be found easily, they wouldn;'t be keen to make
their existence known, would they?

Also, in summer 1992 I went on a trip abroad to Europe by coach, and
on the way out there were a couple a little younger than myself on the coach
a bloke and hius girlfriend. He said things about some bloke who was
never named, who sounded exactly like me - and he made explicitly
clear that our house was bugged, and that a neighrbours house was
bugged (and at work they'd been rep[earting what was said at the
neighbours, so this looks like independent corroboration).
They also said stuff like "at school he was always really streesed,
they found someone from his school and he was a real psycho"
and that "he was in a B&B for one night and they got him", dead right
again, I had been in B&B for once night a few days before this trip
and weatching the news again got a reaction from the newsreader.

Subject: Re: BBC's Hidden Shame

>:some pirate radio station in London in 1991, started listening to
>
>Conclusive proof if ever I heard it.
>
>Of course you were the only person in the office in the whole of Britain

Yeah, but this is the point. Each incident is easily and automatically
deniable along the lines you're taking. But when this happens every
time, and when you get independent corroboration from other people,
then there's no escaping it. For example, immediately after I lost
my job in 91 I went into the local garage to get some work done on the
car, and one of the blokes there said to the other, "so what do you
think of it then? it's getting killed on the radio isn't it"
Now again, you look at that and no proff; you can ask them what they're
referring to and they can say they're talking about something else.

>I know you may be a little paranoid, but I suggest you sit down
>and work out rationally what possible reason anyone off television,
>or radio would have for listening to your conversations. After all
>it must be hard enough to present a show to millions of people
>without the added burden of watching and listening to a single
>person and slipping their phrases into the programme.

These presenters are clever people. They wouldn't be presenters
if they weren't - they're easily capable of reacting to an individual
in this way.

What possible reason? I guess because they think it's amusing to do
so. They know that if you ever tell anybody, without being able to
show any evidence, then the reaction you'll get from just about
anybody will be the one you're showing now.

I realize there are loads of people in England and elsewhere with
the sort of thoughts I've described in these postings; and almost
all impartial observers would say that nothing other than an
go after their private conversations (if they did it to me then I can
do it to them, it's a questions of technical competence and money).
If you were lucky, you might be able to entrap them into admission.
You could of course harass or threaten them back (any coppers reading
this?) but that would be illegal and might get a result quite

different to the one you're trying to achieve. Of course, it might
come out of its own accord given time - if so many people know, if
they have an escape valve in their "subtext" through the media,
will it not cease to be at a covert level, given time? Surely it
is in my interest for it to become overt, since the transgressions
at this time are on their side and not on mine?

Thoughts? There must be some way of breaking the secrecy. This
isn't the first time in human history that a conspiracy has taken
place on this scale, but the truth tends to out. The situation
now is they think they';re "winning" hence have little stimulus
to change the rules - if they started seeing themselves "losing"
things could change drastically.

Mike, if that is your name,

I'm going to try to rationalise what you're telling us. I can think of three
possible explanations for what you are experiencing.

One is that there _is_ a conspiracy against you. As a previous writer said,
though, a lot of these programmes are taped, so it really isn't possible in
some of the cases you've named. Further, why were no bugs found in your
house? Finally, unless you are a political figure or someone else in the
public eye, why would anyone bother? People like me (and I assume you) are
small fry; our contribution to society is likely to be minor. Why would
anyone spend so much money and effort on you?

Another possibility is that you are developing some kind of paranoia. There's
no stigma attached to this; we're all paranoid to some extent, although
perhaps not to the extent that a doctor would call us paranoid. I think
paranoia is quite a straightforward explanation here - you really do believe
that all these things are aimed at you; you see people everywhere trying to
get at you. Logic suggests that this cannot really be the case.

The third possibility is that not even you really believe any of this, and
that this is a "troll". I'm not sure I believe this possibility, but it's
possible.

Anyway, if you want to be sure that you're _not_ going mad, I'd go and see
your G.P. if I were you. If you don't trust him/her, why not see someone
recommended by a person you can trust? If you don't trust anyone any more,
don't you think it's time you got help?

For a troll, the posts are remarkably well-informed on paranoid
behaviour.. you'd need to be one, or be reasonably well-informed on the
subject to sustain the tale... which lead me to my theory...*ahem*...:

An extension to possibility 3 (Number 3.5, perhaps?) is that the original
poster may be somehting like a psychology student writing a term paper
on the net community's reactions to this tale. (Now, there's paranoia
for you! Not only are they listening to/watching us, they're writing
reports about us too...:-)

More likely, though, is that the poster is genuinely in need of professional
help (he has intimated as much, himself) and, as such, he should be encouraged
to seek it.

Newsgroups: uk.misc
Date: Tue Aug 1 10:23:46 1995

>OK, so instead of my posting the same tedious stuff every day,
>why don't you actually read the contents, and make a meaningful
>reply? Something more constructive than those silly little
>jokes about paranoia perhaps? Like what objectively can you do
>to break the conspiracy open, if one exists :-) ? If somebody
>did it to you, what would you do?

But we've *done* that. I certainly have at least. Way back when you
originally started posting and your posts were neither tediously repetitve
nor stupidly long.

But whenever anyone makes any good suggestions you ignore them and start
posting from the begining again. You don't want us to help you - so what do
you want? If you really wanted help you would listen to peoples suggestions
and respond to them. Is this just an attention thing?
But I'll try again, because I'm a fool like that.

>o Tell people about it, go to the police / legal services
> Done that; those around me either don't believe me, or they
>"sort of" believe but can't do anything about it. As for going
>to the police; I did, over Easter. Discouraging. They must be
>familiar with the occasional person walking into a station with
>this sort of story. "If a psychiatrist says you're imagining
>it, then that's what it is".

You haven't yet given any examples of anything concrete to suggest that this
is really happening to you. This, I would imagine, will be the stumbling
block for the police. How can they possibly help you when your only evidence
is a jumbled mess of TV presenters saying things that could be construed as
answers to your comments and the 'feeling' that people are talking about you
and watching you?

I seem to recall that last time this was being discussed someone asked if you
had been to see a psychiatrist about this - after all if this is really
happening then you have can only benefit from being given a clean bill of
health. I don't recall an answer.

> I also went to a firm of solicitors; again, very
>discouraging. Put bluntly, they can't deal with cases where the
>perpetrators aren't well-defined and the existence of the crime

>itself is unprovable.

Well how could they? Who would you sue? The country?

>o so if that option is out, what's left? well, there's the
>"do nothing" option. To some extent this option works. They've
>spent a lot of money and ultimately achieved nothing except to
>force me out of the country - which has been an own goal for
>them, since now they can't do what they were doing in the UK.
>Expenditure of further resources would feed the pockets of
>their greedy contractors, but is a waste of money as far as the
>employing organization is concerned.

So you are no longer in the uk? And this is not happening anymore?

Then let it go. Just leave it alone and get on with your life. Its just not worth it. There is nothing you can do to prove that this happened whether it did or did not. So forget it. Go and explore the net - when people aren't spamming it with useless repetitve posts there's a lot of interesting and worthwhile things out there to see and do. Likewise real life (I'm told *&).

>completely conventional, I have a good academic and work
>record. Until all this started, I had no mental health
>problems; the diagnosis of illness was only after 2 1/2 years
>of abuse. If they did this to me, they could do this to
>absolutely any British citizen. If this stuff gets out, it
>won't be me that has to worry - it'll be them. They take a
>normal person, lie about him, demonise him, try to force him
>into killing himself - and this is in a country where the rule
>of law applies?

If this gets out then *that* will be the time to bring your claims to the foreground.

The only thing ruining your life right now is you, Mike. And the only thing that will make your life any better now is also you. So go and make your life better and show them that they failed.

Claire

==========

>But we've *done* that. I certainly have at least. Way back when you
>originally started posting and your posts were neither tediously repetitve
>nor stupidly long.

Once again we're running into a brick wall. The reason I started posting
was because I couldn't figure out a way out of the situation, and thought
that saying it out into the open would provide a catalyst for one of
those "in the know" (there are plenty in this category, and it's a fair
bet that some of them are reading this) to speak up.

It hasn't worked, yet. A little more aggressive shit-stirring (excuse expletive)
might do the trick. Perhaps Usenet posting is the wrong arena for this sort of
activity; although obviously it does have the advantage of rapid feedback.

Thing is, for people to open up, you would have to provide them with a
reason why it would be in their interest to do so. There's no obvious way
of doing that; to get thinking people to incriminate themselves when they're
safe in denying all knowledge is not a trick I can figure out how to do.

>But whenever anyone makes any good suggestions you ignore them and start
>posting from the begining again. You don't want us to help you - so what do
>you want? If you really wanted help you would listen to peoples suggestions
>and respond to them. Is this just an attention thing?
>But I'll try again, because I'm a fool like that.

A "good" suggestion would be one which had the effect of halting the
persecution, which so far hasn't happened. If you make a "good" suggestion then
damn right I'll stop posting - because then I won't have to.

>You haven't yet given any examples of anything concrete to suggest that this
>is really happening to you. This, I would imagine, will be the stumbling
>block for the police. How can they possibly help you when your only evidence
>is a jumbled mess of TV presenters saying things that could be construed as
>answers to your comments and the 'feeling' that people are talking about you
>and watching you?

Because, as said previously, concrete proof does not exist. If it existed then
I wouldn't be talking to you - if it could be proved, or if those doing it
could be found, they wouldn't be able to continue.

What's happened is all conversation. You can't prove conversation, not without
a tape recorder, and even then you would have to prove that what they meant
corresponded to what you understood.

The psychopath who manages the Applics group at my previous employers
played little word games, not only with me but with at least one other
person in the group; words which rhyme with swear words, words which are
ambiguous, eg "bent", words which rhyme with wank, "sheet" rhymes with shit,
end (how was your weak end? being the standard salutation on a Monday morning).
Sounds childish, most people would easily tell him to fuck off; except to people
with predisposition to depression and the inability to express themselves
(this was before I started taking medication), that sort of nastiness is
not bearable. After ten months of this I was so ill I was crying constantly,
eventually I went into hospital and started on medication. Somebody else he
did this to (over a year later!) got so depressed he took an overdose of
pills, had to go on antidepressants and left.

And where does the "concrete proof" of this trouble exist? NOWHERE. Even if you had physical evidence, even if you had the presence of mind to record what was said, how could you prove what he actually meant by what he was saying? In some cases of harassment you can prove what was done, because it's undeniable. But when the harassment is done with any presence of mind whatsoever, it becomes difficult. In the case of the wider harassment, the people doing it obviously know what they're about - they must have done similar things to other people before in one form or another, and they know what they can get away with, they know what the police will do nothing about.

>I seem to recall that last time this was being discussed someone asked if you
>had been to see a psychiatrist about this - after all if this is really
>happening then you have can only benefit from being given a clean bill of
>health. I don't recall an answer.

Yes. The reply was of the "neither confirm nor deny" variety. Not much else they can say, is there?

>Well how could they? Who would you sue? The country?

Hmmm, now there's a thought... :-)

>If this gets out then *that* will be the time to bring your claims to the
>foreground.

Wrong way round. It won't get out unless I do something to bring that about; remember, it isn't in THEIR interest for THEIR criminality to be exposed. Yelling loudly on Usenet might nudge things along in the right direction.

>The only thing ruining your life right now is you, Mike. And the only thing
>that will make your life any better now is also you. So go and make your
>life better and show them that they failed.

Ignoring them would be bliss, but it's not a winning strategy.

There are going to be more of these posts. Sorry. That's the way it is.

Utter nonsense.

All units are human constructs.

There is no such thing as an absolute frame of reference, or much of
anything else absolute except the value of pi.

There is no absolute quanta of time, length, mass, flux density, energy,
power, angular measure, force, or speed.

>Very unstructured, no proof whatsoever. So why should anyone
>take it seriously? If I said to you, "my next door neighbour eats
>babies", how much credibility would you attach to that?

Well, cos it's true. I was hoping that someone "in the know" would
appear and make some self-revealing comments, but that hasn't
happened. Everyone's keeping quiet. What a pity.

>>This is an agglomeration of articles and replies previously
>>posted to Usenet, so it's a bit hard to read. This posting
>>describes a campaign of character assassination initiated

>Who's character is being assassinated? It isn't clear from the post.
>Are we talking about Grenville Janner? I thought he was a spook
>himself? He's certainly able to hold his own on the issue you cite.

Mine, mainly. The reason for putting that episode at the top
of the posting is that they tried to kill two birds with one stone
at the Beck trial - they simultaneously put words into the mouth
of their invented "witness" to smear Janner, and repeated exactly,
word-for-word, stuff which had been said by and about me.

That was the only occasion (the only one recognizable to me,
anyway) when they went after another target at the same time.
And it's quite lucky they did that - because it could give some
pointers to who they might be.

Presumably there are people still around who were involved in
that trial, and know what happened. Beck might be dead, but the
"witness" would still be around, as would Beck's solicitor.

>>by a group of people or agency within the UK. Although
>>they have never presented their identity, you can draw

>>where the real source is to be found.
>
>The newspapers?

Well, your guess is as good as mine. But what newspaper would
send a team after someone for five years? I don't think so,
somehow. Of course they could, but it wouldn't be in their
commercial interest.

You'd have to look at a corporate entity which would indulge in
activity of this type, and the nature of the contacts they have
narrows down the search.

>>The goons behind the molestation are lower than the paedophiles
>>they use to convey their propaganda - they use the same

>
>Ummm.. Janner is a Barrister, a journalist who writes on a wide
>variety of issues, and a long-standing Labour MP. If he's unjustly
>smeared, he's more that capable of setting the record straight.

Janner blamed Beck for the invention. He didn't say anything about
it having any other origin. Even had he suspected any other source,
he could hardly have pointed the finger without some evidence.

>You say that the media is making similar allegations about you in
>relation to this issue? So, you're accused of child abuse, amd
>the allegation was reported in the media, I assume.

I've been accused of many things although that wasn't one of them.
Most of them have been yelled in my face by people on the street
in London at some time or other. Bit difficult to misinterpret
when that happens.

>What exact;y are they saying about you? (Respond here please. I'm
>leaving the UK tomorrow, so I can't read e-mail.)

It changes with time. Every so often, they sing a new song;
so at one point the allegation was homosexuality, at another
is was low intelligence, then it degenerated into sexual abuse.

<snip>

>>our friends in ITN, last but not least our friends in Capital
>>Radio in London and on Radio 1.
>
>How do you know this? Just from what you hear on the radio?

I can't remember if this was mentioned in the "regular" posting,
but on a few occasions they set me up with people nearby to talk
about me, or more correctly, to talk about somebody who
(in their minds) "resembles" me, with actually naming me.

One such occasion was a coach trip to Europe in June 1992.
The "set up" comprised a guy talking to a vacant giggling female
about "this bloke", who was never named. Apparently "they"
(also never named) "found somebody from his school",
"they" "got" him at his house and at a neighbours, and at
a B&B where their target was for one night.

Apart from that, yeah, from "what I hear on the radio". And
from what I see on TV. (I wouldn't be doing my job as a
mentally ill person properly if the TV and radio weren't
talking to me, now, would I?)

>>Oh yeah, I can see it now. All of them banding together, in a united
>>effort against one man. So ITN, the BBC, and Capital all decide to sit
>>round the table and they come up with idea of breaking into someones
>>house, putting bugs everywhere, listening in to his conversation, and
>>shoving it out on the news everyday.
>
>But why would they do this? What possible reason would they have?

But why get at anybody? Victimisation is the pastime practised against
other people; as the scorpion said to the frog, "it's in my nature".

>Are you aware that what you describe is also a common symptom of people
>who are suffering from a psychiatric illness? Have you been to your
>doctor and told him about this? Did he prescribe any medication? Have
>you been taking it, or have you stopped?

Yes, Yes, and Yes respectively. Still taking it. Doing quite well actually.

>>someone he didn't identify, "you know this bloke? he says we're
>>trying to kill him. We should be done for attempted manslaughter"
>>which mirrored something I had said a day or two before.
>>Now that got broadcast to the whole of London - if any recordings
>>are kept of the shows then it'll be there.
>
>And this is supposed to mean... what? Chris Tarrant is in on this plot
>to kill you? It sure sounds like a joke to me. When you start to get
>ill, the mind often makes connections that seem logical and lucid to
>you, but do not to the rest of the world. This is one of those connections.
>They are usually known as delusions.

This is the problem, and there doesn't seem to be any way around it.
If a clearly sane person reported this persecution, you might believe
him, but probably you'd tell him to go see a doctor to "verify his
sanity". If someone with the illness of which you could argue these
things to be symptomatic says these things, again, you might believe
him, but it would be unlikely - the easiest route is the one you are
taking in the above paragraph. The only way I can convince you of what
I am saying is by giving precise details of what, when, how - and for
most of that stuff is based solely on memory.

To prove it would require an admission from somebody, or else hard
proof in the shape of physical evidence such as tape recordings.
Of course, I don't have that.

>The idea of a "pattern", and the notion that if anyone could look
>through your eyes they would see the same thing is very indicative of
>the onset of a psychiatric illness. Schizophrenia and manic depression
>have similar symptoms. I'm not trying to be disrespectful here.
>This may be an illness and it can be managed by the use of medication.
>If it _isn't_ treated, it can lead to terrible tragic consequences.

I'm quite aware what the symptoms would be, and that the reality
corresponds to those symptoms.

But if anything, that is an argument which could convince you of
the truth of what I'm saying. If they deliberately set out to
simulate the symptoms of schizophrenia - in other words, if they
know through observation that their target is either suffering
from the illness, or is on the borderline and could be pushed in
with an appropriate stimulus, then they can feel safe in what
they do, since once you are registered as suffering from the
illness, people will assign less credibility to assertions that
persecution is based in reality.

That this can happen, and people collude by silence, is absolutely
horrifying. It is all the more horrifying that it can happen in a
country such as Britain which has no history of repression.
Perhaps its happening in the UK is due to the arrogant assumption

of moral superiority on the part of those in the media and others involved - we won the last war and we can keep harping on about German and Japanese war crimes, so we can do whatever we like and we'll be right, up to and including destroying the lives of our citizens (as long as we're not caught doing it).

>>That is the level it's at - basically they show they're listening
>>to what you're saying at home, they show they're listening to you
>>listening to them
>
>But why? And why you? Do you realize how much it would cost to keep

>So, all in all, you couldn't actually do the job for much less than
>a quarter million a year. Over five years. What are you doing that makes
>it worth the while of the state to spend over one and a quarter million
>on you?

Those are pretty much the sort of calculations that went through my head once I stopped to consider what it must be costing them to run this little operation.

The partial answer is, there have been periods when the intensity has been greater, and times when little has happened. In fact, for much of 1993 and the first half of 1994, very little happened. Although I don't think that was for reasons of money - if they can tap into the taxpayer they're not going to be short of resources, are they?

The more complete answer is in the enormity of what they're doing. When countries kill their own people, as a rule, they get found out and all hell breaks loose. This isn't some para shooting Irish teenagers in the back. This is something which permeates English society, which they are ALL responsible for, and which they cannot escape responsibility for.

Relative to the cost to British pride of seeing their country humiliated for the persecution of their own defenceless citizens, isn't is worth the cost of four or five people to try to bring things to a close in the manner they would wish? To the government a million or two is quite honestly nothing - if they can convince themselves of the necessity of what they're doing,

money is not going to be the limiting factor.

>>What possible reason? I guess because they think it's amusing to do
>>so.
>
>What? Spend a quarter mil. a year to amuse themselves? And why not
>change every now and again? Why keep watching you? (Unless you _are_
>doing something, and I don't think you are, though you may have some
>deep, dark secret in your past.)

See the above.

>to say about this? Just to get some more perspective on your perspective,
>so to speak?

Sure, it "leans" towards it. But please at least admit there is a
POSSIBILITY of it being very real. And once you've done that, can
you come up with some thoughts on methods of proof? I may be missing something
in my assessment - there may be a way of proving it, in the face of non-
cooperation from the "players".

Jim:

Well then, we can safely assume you have no belief in God! And,
certainly not a God prone to playing dice in the dark!--but, still able
to follow some rules ... (thanks for that one Cecil)

Well then, that leaves the "Man is God" theory, we will just make up the
rules as we go along ... I have tried that with women--I find most of
them even have rules I must obey ...

<chuckle>

>Hmmm, strange eh.
>I mentioned all this goings on to my boyfriend, who works for the
>British intelligence service, and he assures me this sort of thing
>never goes on.. not ever...honest.
>Though he said the name was familiar...

it does go on, although it's an open question who does it.

Some time ago there were press reports of an Army intelligence person called Jones who claimed Diana and Hewitt had been photographed in a compromising position... he said he'd been doing this as part of an Army unit which had previously operated in Northern Ireland.

Then Hewitt said he'd been told the same thing by some Army people, and that they were threatening to release the tapes unless they curtailed their liaison... as per usual everyone denied everything, painted Jones as the "Jones twins" - not very original in how they deal with their perceived enemies, are they?

You have to wonder how they manage to achieve this sort of surveillance though. Audio you can understand, it's possible to put a microphone through the wall, and apparently there exist devices which will retrieve sound from a laser beam bounced off a window - sounds sci-fi, but there's a well known surveillance electronics company in London which sells these things.

But how would you get video out of a room, unless you had actual physical access in order to plant a device for pickup? We're not talking about looking in from afar, but an actual device within the room. You could either drill through the wall and shove a pickup through; or you could supply a trojan device with a hidden pickup inside; but most likely, you would have to physically break into your target room to plant a camera. That's not an infeasible option; all it means is having your target(s) watched to make sure they're not in the vicinity, then you negotiate any locks on the property and find a suitable receptacle for your device.

The next question is how they defeat the usual methods of counter-surveillance. We had private detectives carry out a "sweep" of every room and the telephone line. They found nothing. That indicates at least four possibilities that I can think of; (this is all guesswork BTW, and probably fanciful guesswork at that!)

1) no bugs (pull the other one)

2) radio-transmitting devices which can be controlled from an external source, ie you can instruct them to switch off when you detect a counter-surveillance sweep taking place

3) hard-wired devices; probe microphones or whatever they're called, things you poke through the wall

4) passive surveillance devices; so you bounce laser or radio waves off a suitable reflecting surface (again, sounds far-fetched but such things may apparently exist).

5) there is a fifth possibility, that the PI's didn't detect an actual transmitting device; there are technologies specifically designed to avoid detection, eg frequency hopping and suchlike. But how much sophistication could you build in to a device which would have to be small enough to be physically concealable?

I guess the real question is to find out who is ultimately behind these "goings on". And if the "great and good" (or the better known, at any rate) can't protect themselves, what hope is there for the rest of us?

Hi Paul,

I consider the following an artificial solution:
>The main alternatives are:
>
>1. Make rec.radio.amateur.moderated an all-encompassing moderated amateur
> radio discussion newsgroup.
>
>2. Keep the topics focused on misc and policy, and come up with a
> better name for our proposed misc+policy moderated amateur radio
> discussion newsgroup.
3. Instruct participants in the use of web tools so that they can
filter out abusive topics or abusive users. Very simple with today's
readers.

Solution 3 can be immediately implemented and requires no further
fragmentation of the news feed. Solution 3 is also democratic
compared to the possibility of the abuse by autocracy.

The point you're missing is that the standard isn't changing with
respect to the frame in which the observations are made. We're
accurately measuring what we're observing in our reference frame -
unless of course you're prepared to prove otherwise.

You missed the point Cecil.

Time never changes in our frame of reference.

The second is always the duration of 9,192,631,770 periods of the radiation
corresponding to the transition between the two hyperfine levels of the
ground state of the caesium-133 atom.

The standard is not changing with respect to a subjective
frame of reference but it is changing with respect to an
objective frame of reference? What is wrong with this
picture? Ignorance of the objective frame of reference
is no excuse, IMO.

How many times have I said standards are arbitrary, Cecil?

That the standards are arbitrary is irrelevant.

That the human defined unit of time called the second didn't exist before
humans defined it is irrelevant.

Time existed before humans and will continue to exist after humans are
long gone.

There is no such thing as a quanta of time.

The human defined unit of time called the second is simply a way to
measure time.

The universe existed for a very long time before humans came along and
defined a unit of time called the second and put a number related to
those units on it's age.

Cecil:

This has become an impossible argument. And, Richards' comment about paying some attention to staying on topic caught my attention.

My point is, with our present state of knowledge and understanding of such things as time and the "mysterious 377 ohms" (not EVEN to mention the permittivity of space) our antenna designs and advancements have stagnated.

It is hard to prove a negative, as you have stated before. So, let us not move forward to prove, rather to investigate--to leave no stone unturned (not to mention to go where no man has gone before!)

Or, look at Roys' program EZNEC. The antenna, by present understanding of the mentioned "standards", has become ALL TOO PREDICTABLE. (not to offend Roy, he has done an EXCELLENT job and he is an asset) It is at the point where we begin to dare advance that progress killing statement, "All is known, all has been discovered."

When things become this predictable, when advancements are up against the wall and stalled, isn't it time to go back and look at these "truths" we began with in the first place? I would like to think a new discovery is but around the corner ... we may not do it, but we can create a forum where it will happen.

What kind of men would allow this to exist?

Warmest regards,
JS

The universe doesn't age one second with each passing
second of subjective-arbitrary Earth time so what good
is any estimate of the age of the universe? A scientist
living somewhere else in the universe will get an entirely
different result. One of the cornerstones of science is
that if the results are not reproducible everywhere at
every time then they are invalid.

You never tire of bringing up the Catholic Church and Galileo, do you?

Sorry, I don't know much about the Church other than they screwed
Galileo and you can shake it twice to clean the bore, but shake it
thrice and you've sinned some more.

Anyway, it appears that either:

A. You don't understand what a frame of reference means in physics.

or

B. You're bored and want to argue for it's own sake.

or

D. All of the above.

Yeah, so what?

The lever hasn't improved in thousands of years other than in the use
of new materials.

The same can be said for cannon and revolver design since about 1900.

When was the last time you heard of advancements in the design of milling
machines, lathes, fork lifts, the CRT, and any number of things?

Technologies mature, get over it.

Oh, and 377 Ohms and the permittivity of free space are not "mysterious"
to the educated.

Because the communications are likely to be line of sight, you could use
inverse square law equations to predict the signal strength.

> Would the FCC procedures still be valid? I wondering how the field
> strength tester would go mobile 30 meters from the radial or

FCC test procedures? How about FAA procedures? Keep in mind that with
balloon launches such as this group does, there are notices issued
warning aviators and air traffic controllers about it's existence. If
you poke something any higher than 700 or 1200 feet in the air
(depending where you are), you're in controlled airspace. You must
notify the local flight service station and provide position information
IN ADVANCE.

Nonsense.

The universe most certainly does age one second with each passing
second within the frame of reference where the second was defined.

If a scientist living somewhere else in the universe uses the same
frame of reference, he will get the same result.

If he uses a different frame of reference, he will get a different
result which can be converted to our frame of reference and the
result will be the same.

GPS satellites are in a different frame of reference but manage to
provide results that agree with our frame of reference.

What I really don't understand is why understanding frames of reference
is so difficult for many evidently otherwise intelligent people.

I was reading the problem as "since the balloon is moving, how can
you even fix on a pattern"

A lot of that isn't so much about field strength as pattern. They want
that controlled. And that's arrangeable when the antenna is fixed.

But if the antenna is moving about, then the pattern will change as
it moves, so you can't guarantee that it won't interfere with that
station in the next town over, while a fixed antenna would allow some
sort of directionality to provide a shadow in that direction.

Reminds me of people using 2M FM in the early seventies, from
small airplanes. They had no problem with a handie-talkie's low
power output, they had all kinds of problems with not being
able to control it so transmitting on a popular frequency would
trigger a bunch of repeaters at one time.

Well, thanks for all the replies. I got my "potato gun/canon" to work well today. I have a remote trigger to set the canon off so if the pipe explodes I wont be hit. Hair spray is the answer. The guys at the local autoparts store had already researched the different brands and had a convicted opinion about what was best. I bought a can of that stuff. 3seconds of spraying works well.

But now I have a new problem. When the thing went off the 4lb fishing line played out for about 8 seconds. It's still connected to the projectile but after seaching the woods for an hour I couln't find it. The trouble is I don't know how far it went. 100ft 100yards or 100miles. The 4lb fishing line is invisalbe from more than a few feet away.

What now?

Tonight I'm making some more projectiles. It's looking like I'm not goint ot be on the air for this weekends CQ 160M TEST.

You really need to try and get your head around relativity. And
understand that what you are worried about doesn't matter a whit.

However, this will likely degenerate into one of your famous "Cecil
against the world" pissing matches as usual.

Babbling word salad.

Then again, there are those without a snowball's chance in hell of
ever understanding what frame of reference means.

Babble.

The universe has aged one second with each passing second within the frame of reference where the second is defined whether or not there was anyone around to define a second and will continue to age at that rate in that frame whether or not there is anyone around who could take notice of the fact.

And since the frame of reference is a defined thing and not a physical reality, it doesn't matter if the Earth continues to exist or not either.

You seem to have a lot of difficulty with this concept.

> > What I really don't understand is why understanding frames of reference

To be accererating, there would have to be a force .

Where would this force be coming from and what pray tell is directing
it?

The speed of light is a constant in all reference frames. If a light
source were to be moving at the speed of light away from an observer,
an impossiblity in itself, the light would still be moving at c towards
the observer.

Actually, the second is defined as a certain exact number of oscillations
of a cesium atom in the same reference frame as the observer. The
transforms of general relativity permit us to predict the behavior of such
atoms (relative to our own observation) in other reference frames as long
as we have a good mathematical handle on their velocity and gravitational
warp.

Hello,
I'm simulating in my schematic an antenna whose representation in
based on s-parameters. I need to add in that schematic a matching
inductor whose model should be s-parameter based too. This inductor is
produced by Murata and I'would like to know if, in your opinion, is
possible to get the dataset of s-parameter for this component in
typical range of frequency. I visited their website but I'was not able
to find that data. Had someone did that before?

At 14 MHz with a rx antenna gain of 0 dBd and no transmission line loss, that would call for an incident field strength of about 78.7 mV/m. Maybe not impossible for some SW broadcast stations and very good propagation conditions?

The maximum nighttime skywave fields received in the skip zones of a 50 kW, non-directional, MW AM broadcast station generally are less than 5 mV/m.

> coming drivers of potential road blocks.

If this application is a real project, and intended for the US, and you need it to "broadcast" to FM receivers over an area that would be fairly useful for this purpose, then a station license will be needed from the FCC.

Unlicensed transmitters in the 88-108 MHz band are restricted under 47 CFR Part 15 to radiated field strengths not exceeding 250 ï¿½V/m at a distance of three meters in all directions from the transmit antenna. The transmit antenna needs to radiate only ~18.8 nanowatts in order to generate that field. FCC OET Bulletin 63 is a good resource for this situation http://www.fcc.gov/Bureaus/Engineering_Technology/Documents/bulletins/oet63/oet63rev.pdf .

> Anyway, I'm supposed to determine the range of the
> FM transmitter by measuring the field strength.

The propagation paths for these circumstances will be line-of-sight, so except for reflections, received field strength will be inversely proportional to the distance from the transmit antenna. A system operating legally under Part 15 would produce a field of about 2 ï¿½V/m at a distance of about 1,400 feet. So if the airborne tx system elevation was 500 feet, its ability to cover a significant area on the ground with useful signal strengths will be reduced.

Hopefully this background information will be useful.

796. L/Series network tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-26 14:51:09 UTC
From: marc <amarcpassy@gmail.com>
Message-ID: <1169823069.024417.273600@v45g2000cwv.googlegroups.com>
Source record: 46460
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

In looking to build a tuner, I was looking at an L-network tuner, with switched inductance. If I also add a switch to make it a series-network (capacitance "before" or "after" inductance), what would be the limitations of such a design? I.e. What types of antennas, or under what conditions would it be inappropriate?

Thanks.

797. Thevenin and s-parameters...

Hello,
I'm have "little" doubt about s-parameter simulations. My
question is very simple but I do not know if the answer is the same.
The Thevenin theorem can be applied to a s-parameter simulation?
That is, if I do a simulation using a port P1 of 50 ohm where at valley
of the generator I've connected 2 impedences, one in parallel Z1 and
one in series Z2. Supposing I obtained S11 at frequency f1. Then I
incorporate the impedence Z2 (at frequency f1) in the port 1 impedence
(using Thevenin), can I obtain the same S11 parameters for f1 fequency?

The part about force is badly worded, I admit.

However, are you saying the speed of light is not constant in all
reference frames?

If so, you are a damn idiot.

Even the speed of sound is fixed in our atmosphere (approx. 770 mph at sea level.) A moving object emitting sound can only "jam" the beginning of the sound wave towards its end, effectively "shortening" that sound wave and raising the pitch--the opposite can also occur.

We call this the doppler effect, it can also occur with light (has a fixed speed in the ether) and yes, even our rf transmissions.

I found that old piece of text when checking up on exactly what type of "discussions" you engage in; what I was pointing out with it is--YOU ARE A TRUE TROLL!

You are, NO JOKE, the real thing!

Because the communications are likely to be line of sight, you could
use
> inverse square law equations to predict the signal strength.

Actually, no, inverse square (free space) will underestimate the
received signal strength. There's also a "height above the ground"
factor that would need to be taken into account for UHF and VHF links,
because the ground reflections are significant on both ends of the
link.

A program called Radio Mobile (google for it) can do the modeling over
your terrain.
Or, you can probably find one of the quick approximations for uniform
terrain. The usual model is called Longley-Rice, but Bullington has a
quick approximation.

Pure babble.

Sound is a mechanical effect and requires a progation medium.

Light is an electromagnetic effect and does not require a medium.

One has nothing to do with the other.

> We call this the doppler effect, it can also occur with light (has a
> fixed speed in the ether) and yes, even our rf transmissions.

More babble.

That is not the doppler effect and there is no ether.

> I found that old piece of text when checking up on exactly what type of
> "discussions" you engage in; what I was pointing out with it is--YOU ARE
> A TRUE TROLL!

> You are, NO JOKE, the real thing!

And you are a true, babbling, ignoramus.

Lest someone believe your ignorant babble:

Speed of light and reference frames

From http://en.wikipedia.org/wiki/Speed_of_light

"One consequence of the laws of electromagnetism (such as Maxwell's
equations) is that the speed c of electromagnetic radiation does not
depend on the velocity of the object emitting the radiation; thus for

instance the light emitted from a rapidly moving light source would travel at the same speed as the light coming from a stationary light source (although the colour, frequency, energy, and momentum of the light will be shifted, which is called the relativistic Doppler effect). If one combines this observation with the principle of relativity, one concludes that all observers will measure the speed of light in vacuum as being the same, regardless of the reference frame of the observer or the velocity of the object emitting the light."

Doppler effect

http://en.wikipedia.org/wiki/Doppler_effect

"The Doppler effect, named after Christian Doppler, is the apparent change in frequency and wavelength of a wave that is perceived by an observer moving relative to the source of the waves. For waves, such as sound waves, that propagate in a wave medium, the velocity of the observer and the source are reckoned relative to the medium in which the waves are transmitted."

Relativistic Doppler effect

http://en.wikipedia.org/wiki/Relativistic_Doppler_effect

"The relativistic Doppler effect is the change in frequency (and wavelength) of light, caused by the relative motion of the source and the observer (like in the regular Doppler effect), when taking into account effects of the special theory of relativity.

The relativistic Doppler effect is different from the true (non-relativistic) Doppler effect as the equations include the time dilation effect of special relativity. They describe the total difference in observed frequencies and possess the required Lorentz symmetry."

Speed of sound

http://en.wikipedia.org/wiki/Speed_of_sound

"The speed of sound is a term used to describe the speed of sound waves passing through an elastic medium. The speed varies with the medium employed (for example, sound waves move faster through water than through air), as well as with the properties of the medium, especially temperature. The term is commonly used to refer specifically to the speed of sound in air. At sea level, at a temperature of 21 ?C (70 ?F) and under normal atmospheric conditions, the speed of sound is 344 m/s (770 mph)."

What is sound

http://en.wikipedia.org/wiki/Sound

"Sound is a disturbance of mechanical energy that propagates through matter as a longitudinal wave."

What is light

http://en.wikipedia.org/wiki/Light

"Light is electromagnetic radiation with a wavelength that is visible
to the eye (visible light) or, in a technical or scientific context,
electromagnetic radiation of any wavelength."

Anything else you would like explained, like where rain comes from?

This is actually being done, not with FM but with television. The U.S. Government (administered by the Voice of America) has, since the early 1990's, been beaming television signals to Cuba as the propaganda station Television Marti. This is being done from an Aerostat Balloon which is about 1/3 the size (in length and width) of a Goodyear-type blimp and is of a blimp shape. It is tethered from one of the lower Florida Keys about 20 miles East (and a bit North) of Key West. It is at an altitude of about 10,000 feet. The signal can be seen in Cuba, but it is usually jammed. These balloons have been used for years before that as low-look radar pickets, notably for drug flight interdiction and are quite visible in several places in the Southwest.

I was a technical advisor to this project back then. I advised on the potential of jamming. This program was advocated by the first Bush administration and had Congressional approval. With that sort of horsepower, the various Federal agencys such as FCC (who had remarkably little to say about it) USIA, NTIA, DOD, FAA, State Dept. and a bunch of others all jumped into line. Several agencies had strong objections to this effort but we were all sat down in the White House Situation Room and told, "The President wants this and he WILL get it." BTW, my role was only advisory, I had no policy capacity whatsoever in this.

A frame of reference based on 1/86400 of one rotation
of the Earth which is only 1/3 as old as the universe?
A frame of reference based on the oscillation frequency
of Cesium when Cesium didn't even exist before the first
super nova? I'm not having difficult with the concept.
I'm just wondering why anyone would accept such a
flawed concept. The 17th Century Catholic Church's frame
of reference was earth-centric. So is our time frame of
reference. Both are equally valid.

Units of measurement are totally arbitrary, what they are measuring isnt. It
is irrelevant how long a second is as long as everyone agrees. Time has
nothing to do with the existance of cesium. The origonal basis for the
second was the roatation of the earth but that is not constant so it was
redefined I believe in the 60s, seems like I remember hearing about it in
HS.

Jimmie:

There is much common sense in what you state.

However, I see us at a point where no more real advances in knowledge
can be made until we do have an understanding of what these arbitrary
units ARE measuring--at present, all we really understand are our units ...

There are a lot of things about the universe we really dont understand, time and gravity are just two. Our understanding of time is just a theory like gravity but so far all we think we know about it seems to work. I dont worry much about falling up when I get out of bed in the morning. Arguing about it is as fruitless as telling someone why an arbitrailly thrown together pile of metal isnt a breakthrough in antenna design. Where do you start??

Could you post the Murata part number? What data DO they have? If they have complex impedance versus frequency, or apparent inductance and Q versus frequency, or inductance, self-resonance, and Q versus frequency, it should be nearly trivial to convert any of those to S11 versus frequency. Over at least a limited frequency range, you could use RFSim99 to generate the S-parameter file from a model based on inductance, Q and self resonance -- limited frequency range only because you'll probably have a hard time getting the Q of the model to match that of the inductor over a wide range.

Cheers,
Tom

The two are entirely different.

Name a place in the universe where the Cesium atom transitions at a
different frequency in that reference frame than it does in our
reference frame, provide the underlying physics to explain it, and
then prove it.

One wonders how you can continue to compare proponents of Eistein's
theories to the 16th century Catholic church and expect to be taken
seriously.

Thanks,

No oproblem with 0 frequency or 0 energy being released from a particle
traveling at the speed of light relative to that partcle.Negative frequency?
all our current laws of physics have just been trashed if we can do that.

I'm glad you agree. That is exactly the mistake that was
made when scientists falsely assumed that EM waves could
flow through nothing. *Every* wave needs a medium in which
to flow.

Jimmie:

Yanno, Cecil is like that, just when you think you have a handle on things--HE chucks a monkey wrench in it!

If you are traveling away from me, at the speed of light, and you are transmitting to me--wouldn't you be "stretching" that rf wave "flat." In effect, what I see is a DC signal (well, actually I don't see anything.) Owing to the doppler effect?

Now, if you exceed that speed of light, what happens to that rf you are emitting? I'll have to think on that one a bit ...

Warmest regards,
JS

Not at all. Assume two planets are traveling in opposite
directions away from a reference point in space. With
respect to that reference point, each is traveling at
3/4 the speed of light in opposite directions. Calculate
the red shift from one planet to the other and one comes
up with a negative frequency.

We are likely to discover some day that gravity is a
function of the relative velocity of the Earth through
the ether. At least that's what my alien buddies say.

Consider that the relative velocity between you two
could exceed the speed of light without either one
of you actually exceeding the speed of light referenced
to a point midway between you, which is thought to be
impossible except, of course, at warp 1.1 on Star Trek.
Tom Paris actually managed 10^10 times the speed of
light but it had severe side-effects. (He was forced
to mate with Captain Janeway) :-(.

Yanno, an analogy has stuck me.

If I know what speed waves travel in water and I stand on the shore of a lake and have a boat, making waves, travel away from me, I should be able to see the first case. Then, when the boat exceeds that speed, I should also be able to see the results ...

Trouble right now is, I don't know the speed of waves in water and I don't have a boat. To tell you the truth, can't even remember what the waves looked like when I have had past opportunities ...

Regards,
JS

You'd have to be able to demonstrate that relativistic effects single out particular units of measurement to the exclusion of others without having an effect on the observed phenomena and all within the same reference frame before being able to substantiate any claim that the result of a particular measurement is arbitrary. Can you demonstrate that?

Cecil:

Exactly, we COULD exceed the speed of light and greater, in relationship
to each other! And, then the behavior of the rf, transmitted between
us, could be observed at greater than light speeds.

NOW. Don't knock Capt. Janeway--I kinda like strong women :)

Hi Marc:

TenTec has made tuners of that design for many years. I have one in my shack and it works very well for me. The advantage of the L-network over the more common T is in ease of tuning. The L-network has only one correct tuning spot for each load. The T network can have several "matching points" some of which can result in large internal losses instead of an efficient match. The L network has slightly less loss when matched than the common T network. The main con for the L network is the requirement to switch the capacitor around to match loads that are greater or smaller than the input load.
Other than the above both networks do the same thing and there is nothing T network can do that the L network can�t and it needs one less capacitor than a T network.
You can see I�m biased to the L, try one you will like it.

> --
> add a <2> before @

Well--yes--assuming no antenna gain and no "gain" effects from
focussing by the ionosphere. Does ionospheric "gain" happen? I'm
pretty ignorant about that. But freespace path loss is
((4*pi*distance)/wavelength)^2, according to my reference. So to
receive 0dBm if 1 megawatt is transmitted, assuming no antenna gain on
either end, wavelenth/distance = .000397. For 40 meters, you only get
about 100km separation. However, I get reports from people I trust
that European broadcast stations on 40m can put a 0dBm signal into a 3
element beam on the US East coast. That's way more than 100km path
length! The 8dB or so gain from the receiving antenna doesn't seem to
fully account for things.

I was just looking for anecdotal input, but some discussion about what
lets signals be as strong as they can be might be interesting too.

Cheers,
Tom

http://en.wikipedia.org/wiki/Relativistic_Doppler_effect

"If the observer and the source are moving directly away from each other
with velocity v, the observed frequency fo, is different from the
frequency of the source fe, as

fo = sqrt{{1-v/c}/{1+v/c}}xfe

where c, is the speed of light."

From high school algebra, fo is always greater than zero.

Nonsensical question.

No one has ever stuck a themometer in the sun either but we have a
pretty good idea what it would read if we did.

We have absolutely no reason to expect the Cesium atom to act any
differently in another reference frame, and variety of reasons not to
expect to be able to chill it to 0 degrees Kelvin.

Babbling nonsense.

http://www.bipm.fr/utils/common/pdf/si_brochure_8_en.pdf

"Unit of time (second)

The unit of time, the second, was at one time considered to be the
fraction 1/86 400 of the mean solar day. The exact definition of
?mean solar day? was left to the astronomers. However measurements
showed that irregularities in the rotation of the Earth made this an
unsatisfactory definition. In order to define the unit of time more
precisely, the 11th CGPM (1960, Resolution 9; CR, 86) adopted a
definition given by the International Astronomical Union based on
the tropical year 1900. Experimental work, however, had already shown
that an atomic standard of time, based on a transition between two
energy levels of an atom or a molecule, could be realized and
reproduced much more accurately. Considering that a very precise
definition of the unit of time is indispensable for science and
technology, the 13th CGPM (1967/68, Resolution 1; CR, 103 and
Metrologia, 1968, 4, 43) replaced the definition of the second by
the following:

The second is the duration of 9 192 631 770 periods of the radiation
corresponding to the transition between the two hyperfine levels of the
ground state of the caesium 133 atom.

It follows that the hyperfine splitting in the ground state of the
caesium 133 atom is exactly 9 192 631 770 hertz, ?(hfs Cs) = 9192631770 Hz.

At its 1997 meeting the CIPM affirmed that:

This definition refers to a caesium atom at rest at a temperature of 0 K.
This note was intended to make it clear that the definition of the SI
second is based on a caesium atom unperturbed by black body radiation,
that is, in an environment whose thermodynamic temperature is 0 K.
The frequencies of all primary frequency standards should therefore be
corrected for the shift due to ambient radiation, as stated at the meeting
of the Consultative Committee for Time and Frequency in 1999"

Go argue with the standards people.

Are you serious?

Where is your proof cesium didn't exist between the time of the big
bang and the first supernova.

Even if true, the current calendar didn't exist before 1752.

So how could we possibly calculate George Washington's birthday?

There are other entropic processes that can be calibrated against the
cesium.

Relativistic effects certainly single out measurements
of time - also length in the direction of velocity.

It has been demonstrated numerous times that the velocity
of a clock affects the length of its second. What is
the velocity of the cesium clock on Earth?

Sort of blurs the line between the plausible and the absurd, Cecil.
The fact that two things might share a particular trait does not
eliminate their differences.

Have you ever heard of the fine structure constant? You had best check into it and how it can be verified from a distance, a very very long distance.

You might as well give up.

Every year, at probably every college, the entry level physics classes, math classes, CS classes start up full. At the end of the quarter or semester most are only 25%-50% full--those students suddenly decided to follow another course of study and are consulting with their counselors.

So, sometimes, it is that way in life ... but you sure got determination!

Now, that is quite easily proved to be FALSE.

The earth is 25,000 miles in circumference, it makes one revolution a day.

25,000mph/24hrs is over 1,000mph. As you sit there typing you are
traveling over 1,000mph, and so is every cesium clock on earth.

Simply Google "zero-point energy". Here's a quote from
"Alpha and Omega", by Seife. "In the 1930's, though,
quantum physicists discovered, much to their surprise,
that the vacuum isn't ever truly empty. It is seething
with activity, filled to the brim with particles and
energy. ... Empty space is an incredibly complex
substance, and scientists are just beginning to
understand its properties."

David:

If there is one thing you will have to learn, DON'T TRUST MATHEMATICIANS!

Think about it man, what would they have told you before the "Quantum Effects" were discovered, if you had suggested such a phenomenon? ... I bet they would have told you, you were nuts, and gone on to prove it mathematically! In some situations, mathematicians are barely better than tea leave readers.

For about ten dollars in PVC pipe & cement, you can build a "spud gun" in about two hours. It's a novelty cannon which shoots raw potatoes. If you had a length of string laid out on the ground (for easy lifting), a potato lofted out of the spud gun would carry the string hundreds of feet Thread the end through the potato and secure it, perhaps with a coat button.

Although I have never shot a potato that had anything in it or through it, I can personally attest to sending potatos high and clear hundreds of feet. The propellant is ordinary hairspray. (Must use flammable propellant; not all brands do.) The igniter is usually the spark lighter from a barbecue grill or discarded stovetop.

The thing does not build itself; it requires some effort and craftsmanship ... but what are we? Are hams not a creative and resourceful bunch?

In some areas, the law regards a spud gun as a weapon, despite the fact that nobody has has ever used one to stick up a liquor store, etc. Check with your local PD before showing up at Field Day with your new spud gun.

Searching "spud gun" on google.com returns 136,000 links. That should keep you out off the street for a while.

I believe the thevenin theorem applies to s-parameter simulation provided
you assume the amplifier (generator) is perfect Class A and perfectly
stable. You need to be aware of where the load is located on the
transmission (1/4 wave? Not sure what you mean by 'valley'). See
http://www.sss-mag.com/pdf/arrl_circles.pdf

< snip >

I read the request and I'm not sure how to respond. Yes, I would like to see a NG that had the politics and flames flushed out of it by a "duty roster" of moderators. However, I'm bothered that it is proposed to *supplement*, not *replace* the other newsgroup. How could I be sure that some (valid) posters weren't behind in the old, abuse-filled group, toughing it out???

What I'm saying is that I want a clean break. If I have to check *two* newsgroups as a substitute for previously having had to check one, that's unfortunately not an improvement.

If my dilemma is too obvious and I shouldn't have bothered stating it, I'm sorry.

Here is another Cebik design.
<http://www.cebik.com/vhf/32m.html>
Wide band 6 element 2M Yagi. I built one using a fiberglass electric
fence post for a boom and 1/8" brass rod for the elements. Works good
for the price.

Leave the old group for those who want to wallow in the problems.

The simple solution for most of us will be to simply ignore or even delete
the other groups.

An example of the conflict between show and tell. Surprisingly you
offer to neither show, nor tell what happens... which leaves us with
your statement:

>>I can just imagine attempting
>> logical measurements ...

Luckily, those who practice the trade have skipped the part of
imagining and just accomplish it instead.

>This gives a "glimpse" of what I mean, the above was vague ...
>
>http://www.newton.dep.anl.gov/askasci/phy99/phy99194.htm

Given the reference (a painfully pretentious website with as much
armchair theory offered as in this thread), you must have misspelled
vogue.

The forced argument (a strawman at that) of motion ceasing went out
with fringe topped surries. Now THAT (motion? what motion?) is vague
in the extreme given there are a considerable number of dynamics that
occur at the 0ï¿½K atomic scale. Are we suppose that electrons in their
orbits at 1ï¿½ï¿½K will collapse into the nucleus (permenantly frozen into
inaction) with the final chilling tweak? What a larf!

These akademik arguments only need the added stipulation that you have
to exhibit an absolute zero beer cooler that will hold the temperature
throughout the Super Bowl.

From: "Fields and Waves ...", by Ramo and Whinnery:
"It must be emphasized, as in any Thevenin equivalent
circuit, that the equivalent circuit was derived to
to tell what happens in the *load* under different
load conditions, and significance cannot be automatically
attached to a calculation of power loss in the internal
impedance of the equivalent circuit."

Power loss in the internal impedance of the Thevenin
equivalent circuit is related to the s-parameters.
|s11|^2 is power reflected from the network input
divided by the power incident on the network input.

There is a medium that does NOT have Nitrogen, Oxygen, Hydrogen, and noxious carbon based gases. That medium is not compressed by the effects of gravity. Any molecules present have very large inter molecule dimensions, maybe even miles.

The medium does have the presence of EM energy in the form of x-rays and gamma rays [among other more exotic energy forms], it also contains ionizing particles [neutrons, protons and electrons], it does support gravitational fields, and it has both a dielectric constant and a permeability. The ratio of dielectric constant to permeability is approximately 377 ohms.

This medium supports EM radiation from deep space to the local earth. What do you choose to call it?

I'm not sure: Is this the same (or at least related to) W/m^2?
The problem I see with these is that, as distance approaches 0, KW approahes oo and what I'm looking for shouldn't be greater than the transmitter's erp.
What got me on this idea, is a few weeks go I was visiting up in the NH White Mountains and was checking out the AM/FM bands (I'm a radio geek! P=). When I got home, I went to the FCC site to create a bandscan of the area. The designation used was the radius from a point.
I quickly realized that this was less than ideal, as--using 100 km radius, as an example--100 W stations at that distance would be listed along with 50 and 100 KW! What would be much more useful would be a listing of stations that provide--st least the theoretical baseline value (i.e., not considering intervening local terrain or one's receiver sensitivity and antenna gain)--a given mV/m or mW at that point (thus listing 100 W stations out to 15 km, whereas 50 KW stations out to 75 km and 100 KW to 130 km would be listed).
Think of it this way: If you turned on a 100 W lightbulb in the middle of a field at night and held a book page right up to it, you would be able to read it clearly; if you moved about 10 feet away (with the book page still facing the lightblb, unobstructed), you would have difficulty trying to read it, as only about the equivalent of (e.g.) 50 mW of light may be hitting the page.

This post is concerned with the general philosophy of moderation in
general, and would be more appropriate for news.groups. Please
restrict your discussion to issues specifically relating to this
proposal.

Your submission has been rejected because it is off-topic in the
newsgroup news.groups.proposals. This newsgroup is for the
announcement, discussion, and development of active proposals for
changes to the Big 8 hierarchies, as documented at
<http://www.big-8.org/>. Discussion begins in news.groups.proposals
when the Request for Discussion (RFD) is posted in
news.announce.newgroups and continues until a decision is announced.

Common topics that do not belong in news.groups.proposals include:

- Discussion of world events or "the news" - see talk.current-events
- Proposals for alt.* or other non-Big-8 hierarchies - see alt.config
or the appropriate regional config newsgroup
- "How do I do X with my newsreader?" - see news.software.readers
and/or news.newusers.questions

The charter of news.groups.proposals is at
<http://www.big-8.org/~ngp>.

Please direct your queries to ngp-mods@ngp.big-8.org.

Thank you,

- Moderator.

To Whom It May Concern:

Just so you have a complete picture of Paul W. Schleck, I took the following from one of his posts in news.groups.proposals:

"Mark Morgan, KB9RQZ, is correct that all of our proposed moderators and consultants hold the highest class of Amateur Radio Service license in their countries (Amateur Extra for the U.S. team members, Class A or similar in the case of Jack Cook, who holds both UK and Australian licenses). However, that doesn't mean that we would be judgemental or unfair to other classes of license. We would certainly be open to adding moderators to our team that hold other classes of license. We will certainly decline articles that are disrespectful to or prejudicial against other participants for any reason, including license class. We would prefer to judge ideas, and take posts at face value, rather than prejudge individuals and credentials in a vacuum."

Now that just speaks volumes about this man, his caliber, his "ethical standards", etc. Now, doesn't it?

Gawd! I feel sick ...

Warmest regards,
JS

Schleck is all about self-aggrandizement. His posts are all about himself.
Read his posts, the few that he sends. Paul is convinced that he, and only
he, has true insight into Ham matters and that he, Paul Schleck, knows
better than us, the Great Unwashed.
Does the term, "Stuffed Shirt" come to mind?

Here is what my response to Mr. Schleck would be on his proposed moderated newsgroup:

Mr. Paul W. Schleck:

I would question your ability to be a fair and just moderator. I have participated in the rec.radio.amateur.??? newsgroups, I have witnessed your abilities and goals.

There, I have seen you and your extra class henchmen attempt to constantly steer the course of its' flow, intimidation and threats have often been your tools. I have watched you and others look down upon other amateurs who will now be allowed to take a "No Code Amateur Exam." In no way have I ever seen you be even close to being "fair" or "just" in your opinions, judgments, statements, etc. I have heard many in that group call the present amateur exams "dumbed down."

Here, you have blatantly lied as to your purposes. You seek a forum where a very limited band of ideas, concepts, beliefs and discussion can take forth. You seek to establish a "class based newsgroup", this class system will VERY MUCH depend on the ancient art of morse code and the amateur exam.

If any here doubt, they only have to sift though the old posts and check past posts of you and those you name as would be-moderators and they will know. What I say, I say with great belief.

You wish to establish a "masonic temple type of brotherhood" here in the public newsgroups. You and a few of your cronies wish to establish tight and strict control over this group. And, from what I can see and guess to your goals, you do this SOLELY for the purpose of stroking your own egos.

Many of the "weirdos", hecklers and vulgar individuals in the other amateur groups are due to you and those sharing your same views and using your "street smart" methods--in effect, your "control freak" attitude and "better-than-thou" stance has created them.

It would serve justice if you were forced to stay and learn to "get along and play well" with the other "children."

Your words show a fine demonstration of stealth and deception; I don't believe I have ever seen a better example than you have presented to us here. I certainly would nominate you for the "Silver Tongue Award."

However, I would certainly NOT vote to allow you to slink and sneak off from the tragedy you have helped to create.

Although you make this request and proposal out of your personal need to feed your ego, and surround yourself with those who would feed your ego for you, and "live in your own little world", I think it would be a crime to allow you to do so.

The potential you have to abuse this proposed-moderated newsgroup to the detriment of others demands it should not be allowed ... I for one would vote NO, but then, you already knew that ...

Regards,
John Smith I

> stations out to 75 km and 100 KW to 130 km would be listed).

Using the known ERP from the transmit antenna it is possible using various algorithms to calculate the field strength that will exist at a distant point for some defined condition(s). The FCC has done this for AM/FM/TV broadcast stations, and the techniques are available to the public via the FCC's website. Various broadcast-oriented commercial software programs also are available to do this, although they are expensive.

For AM stations, the distant field is a function of the frequency, ERP, path length, ground conductivity, terrain roughness, the ionosphere, and the time of day.

For FM/TV stations, distant field is a function of ERP, the heights of the transmit and receive antennas, reflections, atmospheric conditions, path length, and the terrain profile along the path.

These are not simple relationships. For example, in order to provide essentially equal signal strengths over most of their useful coverage areas, the ERP needed from an FM station with a "high" antenna can be much less than if the antenna is lower. Here is a plot showing this...
http://i62.photobucket.com/albums/h85/rfry-100/ClassBCompare.gif

Unfortunately, there is no simple solution answering your queries.

marc,

I am building something very similar to tune up a portable vertical
for use on a steel-hull narrow boat, 10m through to 80m. In my case
a centre loaded 3.3 metre vertical.

You don't say what sort of aerial or what bands you are going to use
but the following should tune most wires and verticals:

Coil: 100 turns of 13 AWG (15 SWG) on 2 inch diameter tapped every
10 tuns. Use a 12 way switch and have one contact to short out the coil.

For the variable cap use a two gang 500pf+500pf with a switch to
switch in the second 500pf and another switch to bring in an extra
1000pf.

Finally another switch to switch the caps from TX/RX side to antenna
side.

Because I will be using a tapped centre loading coil the inductance
needed in my ATU is much less than the coil I suggest above. In my
ATU the cap will be on the RX/TX side of the coil for 80m,40m & 20m
with no coil required on 20. On 80 I also need the extra 1000pf.

By the way, the above is designed and I'm in the process of building
the antenna and ATU - we'll see what happens when I try it out!

Charlie.

John,

I don't see a serious problem with Paul considering your quote or
anything else that I've seen so far.

Let's see... He clearly says that we are not going to require a
specific licence class to be a moderator. That seems fair.

So Where's the beef in your quote?

I can tell you that nobody in the team even noticed that we all where
extras until Mark brought it up. So to my knowledge that was not a pre-
condition for acceptance in the team. I do recall that they needed to
be Hams, but that seems reasonable. I was there from the start of
this, being responsible for setting up the mail reflector we use as
well as setting up the shell account we use for the moderation
software, so I should know.

It seems to me that you guys just oppose the creation of the moderated
group and you have chosen to engage in personal attacks on the
proponents in an effort to keep it from happening.

This is the best you can do? Do you have any real evidence here?

Dee:

There I agree with you 100%. The vulgarity and sheer non-sense makes me
embarrassed for them. I cringe at the mental state they must exist in
to wish to provide such a display in front of women and younger users here.

I fear that this does not just exist in the newsgroups, here with us,
but also is becoming "something bad" in America :(

I can only admire you in finding the tools and having the determination
to be here with us in spite of all that non-sense ...

Warmest regards,
JS

929. Re: Shooting a wire over a grove of tall trees. What works?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-28 16:46:49 UTC
From: AC7PN <brunius@rockisland.com>
Message-ID: <1170002809.237076.120800@v33g2000cwv.googlegroups.com>
Source record: 46343

The canon worked pretty well after a lot of "revisionizing" of the design. I now have a 1000ft inverted V antenna. I runs on the tops of the trees and is stretched to the very tip top of my 80ft tower on the hill top. The coax runs about 400 ft through the woods to the Western terminus of the V. To give a counter poise I ran three 120ft radials from the starting point of the coax and the V. It probably needs more radials but it doesn't need as many as a 1/4wave vertical because the driving point impedance is about 10x greater than the vertical. So I have a home brew 500ohm to 50ohm transformer at the driving point to match the coax. It loads up with a less than 1.8:1 SWR from 1.8 MHz to 29MHz. It is slightly directional to the East according to NEC simulations.

Running this antenna was fraught with frustration. I used 4lb test line shot from the canon. Missing was frequent and that light line would be blown by the wind into trees that it shouldn't be in. The line would often break before getting the job done requiring redoing. I did pull 40lb test before pulling the insulated wire. The wire is 8 #22 conductors in a grey UV resistant ribbon.The antenna wire got stuck in the guys of the tower a number of times requiring climbing the tower 3 times. (That reminds me I have one guy on the tower currently disconnected.) It seemed that the whole project was fighting me tooth and nail.

It works though. I used it in the CQ 160M CW contest this weekend. I couldn't stay up very late being exhausted from building the antenna so I only worked about 6 hours total over two evenings. Made 115 contacts. I'm not so hot at CW. I can answer a CQ OK but if I call CQ I get all panicked and fail to operate especially when three guys answer at once at 35 WPM.

Hi Dave,

You have been snookered into answering a complaint manufactured (as
usual) from the misapplication of relationships. The resonance of
Cesium is not a function of time. Time is not a function of Cesium's
resonance (the incorrect correlation drawn, to which you are
responding).

There is no dependency between the two. It is our dependency in our
usage of one to measure the other. The sophism above is much like
saying sound did not exist before someone was close enough to hear the
falling tree. The excitation of gas molecules we call sound existed
long before the appearance of the first amoeba, much less apes in
falling trees. Both sound and time are phenomenological terms for
simple and rational physical processes that exist without dependence
on us.

Sufficient data already exists on the poison content of rattlesnakes. In addition, don't lump all snakes with rattlesnakes. The common garter snake is quite harmless.

In addition, the rattlesnake forms a useful role in keeping rodents and
other small vermin under control.

Sensible people leave them alone and make sure that the snakes don't come
into their immediate area.

Cecil:

I for one think it has already been shown, we simply do not understand time. Given that is correct, how can we possibly know if the "vibration" of cesium is a function of it--heck, maybe if we ever achieve in stopping the vibs of cesium, time will stop? <grin>

The problem here is in construction of a "true ruler" to measure with ... of course, we always have our "units" ...

937. Optimum length for ladder-fed dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2007-01-28 19:43:12 UTC
From: Rick <reply.in.newsgroup@spam.no>
Message-ID: <csupr2phvr9agtma38ga6m5rrg2rifi1id@4ax.com>
Source record: 46351

I'm planning a dipole installation fed with ladder line and a
wide-range antenna tuner.

I'd like to be able to use it on 160 through 10. A half wave at 160
meters is a bit under 260 feet. Is there any particular reason I
should limit its length to 260 feet? I have enough room to make it
about 320 feet... any particular reason I shouldn' t do that?

Thanks...

Rick

It's pretty obvious that frequency is a function of time.
Velocity is a function of time. Time is also a function
of velocity. Velocity is a function of length. Length is
also a function of velocity. Go figger.

The optimum length of feedline for feeding a 1/2WL dipole
on 160m is 1/2WL, i.e. about 233 feet. If you make the
dipole longer than 1/2WL, the optimum length of feedline
is less than 1/2WL which may be a benefit.

Cecil:

In our present use and construct of time, absolutely.

I have a bit easier "time" of "seeing" things "shorten" as velocity increases, my feeble brain strives for even that. (waves shorten as they are emitted by objects with velocity ...)

Still, I wonder ... and I know, that with a buck still won't even buy you a decent cup of coffee.

Warmest regards,
JS

You might give some consideration to radiation patterns at the higher frequencies where greater lengths will produce more pronounced lobes and nulls and reduce broadside radiation. You might check cebik.com for further information.

Chuck

Your impression of Paul is completely wrong. He is singlehandedly
responsible for the creation of the entire rec.radio hierarchy. He
wrote the charters, solicited the calls for discussions and calls
for votes for each and every rr ng.

It was either Paul or Brian who wrote the Usenet software that's
universally used to carry the newsgroups. (Paul, help me out
here; that seems like a century ago...)

No 73 for you,
Jeff KH6O

The couple of times I have tried a long antenna like this optimization
of the antenna was mostly finding a length the tuner was happy with on
all bands. IF you have a better tuner than my MFJ you may not have
this problem. Check Cecil's website, Hes the man when it comes to no
tuner antennas.

Since you are using ladder line (assuming you use a suitable gauge for the power transmitted), the dielectric and resistive losses losses are insignificant even at relatively high SWR. I doubt it matters much whether your feedline is 100 feet or 320 feet; most relected power will still get transmitted out and not be absorbed as heat.

Alas, the only software that's used regularly on Usenet that I had a
hand in was auto-faq:

http://www.novia.net/~pschleck/auto-faq/

Though Brian did have a big hand in the early history of the Info-Hams
mailing list, from which the amateur radio newsgroups owe their origin
via a gateway.

So some people are saying.

And we still get to see parts of the universe that were close to us post-
inflation, though the universe is really too opaque at that distance to see
the really early stuff. But we're nearing the threshold where cesium would
be rare or non-existent. In short, we're SEEING some of those early
supernovae that made it in the first place. Several cosmologists think
that's the cause of the gamma-ray bursts we're experiencing.

Thank you for your comments,
I'm doing some calculations and simulations in order to verify if I can bypass representation problem of s-parameters in other ways rather than the Thevenin one.
There is one thing I'd like to submit to your attention, the known formula
S11=(Zin-Z0)/(Zin+Z0),
where Z0 is the port impedance and Zin the load, does not works if you consider Z0 not pure real (usually 50 ohm) but composed by a real and an imaginary part i.e. Z0 = a+jb.
Are there other known formulas for S11 for Z0 real+imaginary?

Camelot

One answer as to what the optimum length of feeder should be is 'exactly
equal to the distance between the antenna feedpoint and the antenna
tuner'.

Being serious, be aware that one of Cecil's 'fortes' is the avoidance of
tuning unit losses by using a particular length of feeder, so that the
antenna plus feeder system naturally presents a good match for the
transmitter. On a given frequency, every length of antenna has an
optimum length of feeder, so you need to switch in the appropriate
length of feeder for each band. There is a lot of debate about how much
power you lose an antenna tuner. You may, or may not, want to consider
using this technique.

Your question was actually whether 320 feet would be better than 260
feet. When you go above a halfwave, the theoretical 'donut' polar
diagram starts to break up, but I doubt if you would see much difference
in the performance. Unless the antenna is pretty high above ground,
most of the radiation on 160m will be at a fairly high angle. A low
halfwave is fairly omnidirectional, regardless of the orientation of the
antenna.

Of course, on the higher frequency bands, the radiation will come
increasingly more off the ends of the antenna than broadside. On 10m,

it will probably be very directional, especially if the antenna runs in
a straight line.

Cheers,
Ian.

And at some extreme impedances (accompanied by extreme
SWRs) losses mount in the tuner and balun if not in the
transmission line. I have a rule of thumb to keep the
ladder-line SWR below 25:1 which probably fits with
your "relatively high SWR" statement.

It's also not an either/or choice. Without a tuner, the
ladder-line length selector needs to be able to be
varied in one foot increments from zero to 31 feet.

Since I bought my IC-756PRO with its built-in auto-
tuner, I only switch between three lengths of transmission
line and allow the autotuner to do the rest. So now I
have a hybrid system, still not requiring a full-range
antenna tuner.

I've submitted a magazine article to "Worldradio" magazine
about a dipole that works very well on 75m, 40m, and 17m
without a tuner and without changing feedline lengths.

Yes, time is about as much related to the vibration of a cesium atom as it
is to the pendulum im my grandfather clock.

Body handling: HTML body converted to readable text

Bob, ya did good.... You got an interesting new antenna up... You got your CW dusted off... You had fun in the process...

Don't worry about your CW.. Keep jumping into the weekend contests, even if only for a half hour... The biggest skill in handling multiple callers is learning to latch onto a specific sound and mentally ignoring the other callers... Only practice can teach your brain that skill... Just keep jumping in... Before you know it you will run a frequency without giving it a second thought...

I can't stay up all night anymore either... That is where having a buddy to operate with helps...

Hi Jimmie,

How very true. There is quite a bit of fluff about cesium. So much
so that you've hit the nail on the head with the pendulum.

Dare we anticipate those who will crow that there was no time before
the pendulum swung? Or that if one swung on the moon, this
demonstrates proof positive how time varies? FEH! The pendulum does
not make time, nor does time push the pendulum. There is no
causality.

No, Time is dependant on sand! Before the pendulum there was the sand
clock - aka Hour Glass. The ancients long ago recognized that if they
didn't keep turning the hour glass, that the end of time would come
(in eastern philosophy this was transmuted into the towers of Hanoi).
This, in fact, was the origin of the honorable office of the clock
watcher - his mission was to turn the glass before time fully ran out.
Of course, over time (an irony), this noble occupation became
prostituted through mechanization, and the office holder of clock
watcher became an object of scorn and ridicule. RIP

Some may argue that sand has no causal relationship with time at all,
but they are sadly mistaken. Simple observation will reveal that if
you cleaned your carpets last week, they need cleaning again of all
the sand (dust, dirt) that has descended into their fibers.

Run your finger along any bookshelf to witness this vivid proof. Sand.
Anyone who lives with a wife who keeps bookshelves (bric-a-brac,
picture frames, your shack) so clean of sand can agree that their life
is condemned to a timeless purgatory.

Look at any beach, the sand was once a mountain and a mountain it will
become again (dunes are the modeling software). Naturally you won't
be around long enough to watch all the sand do this, as this hour
glass measures a different period. The proof of this observation is
found with those who go to the shore for vacation, and at its end look
plaintively across the beach and wonder:
"Where has all my vacation time gone?"

If there had been no sand, there would have been no summer vacation at
the shore. Sand's causal tie to time is absolute and irrefutable.

Why is it always some weird, out of the way atom they play with
instead of a main-line, every day used sort of critter?

Krypton. . . Cesium . . . What ever. Why not Oxygen? Carbon?
Even good ol Iron??

Another thing, as it was explained to me, first the electrons are
ghosts to begin with which pop in and out of existence at a whim.
Second, if I had the nucleus of an atom in my hand, and it was the
size of a medium orange, the closest electron would be some where
around 38 miles away. . . `Lots of "Nothing" in between. So, when you
get down to 0 Kelvin, that's where all the shaking around stops, well,
it slows down enough to stop the harmonic vibration, but it also seems
to me that the electrons quit popping in and out of existence then
too. Hence the lack of unbalanced vibration of the missing, counter
balancing electrons. (Much like missing a tire weight at 70 mph on
the freeway or so I would believe.) SO if everything settles down at
0 "K" and starts working properly, why is it so damn hard to achieve?
It seems to me that everything would try to achieve the balancing
point, . . Equilibrium; Being that matter abhors a vacuum to begin
with. There has GOT to be an antagonist stirring the pot somewhere
from behind the scenes!! . . . Gravity?

That was some explanation. It raises one of two questions. Did you
understand it? Or did the explainer?

>it also seems
>to me that the electrons quit popping in and out of existence then
>too.

Does a 2 year-old ever settle down? Short of their already being
asleep, why is that so hard to get them to bed?

>It seems to me that everything would try to achieve the balancing
>point, . . Equilibrium; Being that matter abhors a vacuum to begin
>with. There has GOT to be an antagonist stirring the pot somewhere
>from behind the scenes!! . . . Gravity?

People do a fairly good job of gumming up the works. Heisenberg
introduced us to the notion that when we bother to look, everything
changes. A pyramid balanced on its point is in an equilibrium, but
that is not the same as it being in its lowest energy state, also an
equilibrium. Not all equals are equal (credit George Orwell).

Frank has already provided you with links to (I presume)
transformations to other linear two-port representations.

But I'm curious. Why do you think that the formula you wrote above
doesn't work when Z0 is complex? In what way do you think it does not
work?

I'm also curious why you would pick a complex reference impedance for
S-parameter work, but that's really a different issue.

Cheers,
Tom

You would do well, too, to keep in mind that the data, especially for unshielded inductors, is only an approximation. The inductance and other parameters depend on exactly how you have mounted the part, and what else is around it. If you expect things in the real world to conform "exactly" to your model, you will be disappointed. You will find, for example, that Q changes with temperature, as well as with frequency, since the wire resistance changes with temperature. Expect the Q to change about -0.2% per degree C, which may not sound like a lot until you consider the effect of a 100C temperature rise, which can happen in some equipment.

If you can use a vector network analyzer to actually measure one of your parts (or even a set of them, to get statistical information), that would be wonderful. Many modern VNAs will output an S-parameter file that you can then use in various software for simulations and modelling.

Be a little careful about RFSim99--though I recommend it, it does have some problems in the area of saving and using S-parameter data. In particular, it expects a particular format for input, and on output, check carefully that the conversion was done correctly (something about using 10log(ratio) instead of 20log(ratio) for dB magnitude...).

Cheers,
Tom

So, all this bluster boils down to your opinion?

Do you have any proof that Paul has lied or is this just rhetoric
designed to sway folks away from the Moderated group?

You insist on painting with a wide brush too and would try to sling
mud on all of the proponents named in the RFD (which includes me by
the way..) so I would ask for more proof and a lot less of your
opinions here.

You are entitled to have your opinions and voice them, just don't try
to maintain them as facts until you can offer proof.

In MY opinion, Paul is who he claims to be and the intent of the
proposed moderated group is what the moderation team and advisers have
agreed it would be. It will be fairly moderated but kept on topic and
it will eliminate the constant barrage of personal attacks and the
other garbage that does nobody any good. Of course, this is just
opinion and will have to remain so until we have the new group to
demonstrate that we are being fair.

By the way... I've personally known past members of the US Senate, and
I'd not be too quick to paint them all as liars. The man I knew was
very much the same in person in public as he was in private and he had
no need to lie about anything to get elected. The people elected him
to as many terms as he was able to serve because I believe that in the
long run principle, morals and ethics matter to the average person,
not rhetoric.

Actually, characteristic impedance Z0 is assumed to be 50 Ohm, 300 Ohm or 75 Ohm (etc.), based on the type of transmission line, under the assumption that the line is "lossless", thus in theory only it only considers the complex components.

For a lossless line, Z0 = sqrt(L/C)

In reality, the resistance (conductance) must be considered, where:

Z0 = sqrt((r+jwl)/(G+jwC))

Rick,

It seems most people want to discuss optimum feedline length, though that was not your question.

It turns out that it is quite challenging to obtain good efficiency from a dipole less than about 35% of a wavelength long in the type of configuration you propose. That sets a practical lower limit to the length of the radiator.

On the other hand, the pattern changes with longer length. Probably the most significant change occurs at greater than about 1.25 wl where the pattern breaks up into additional lobes. Another respondent suggests such pattern changes occur at greater than 0.5wl, but that is wrong. So, this effect might set a practical upper limit if the pattern is an issue on 160m or a higher band if you intend multi-band operation.

So, if you made the dipole 320', it is 0.58wl on 160m, and 1.17wl on 80m. The pattern will have two clear major lobes on both bands. You can't make it short enough to avoid pattern break up on 40m without degrading efficiency on 160m (though by only a small amount if you used 1.25wl on 40m).

As far as feedline loss, you know whether it is insignificant when you have calculated the magnitude. Though others suggest that ladder line is (always) insignificant, it is the loss in the ladder line that drives the 35% minimum practical length discussed above.

So, the choice depends, and probably mainly on whether you want to use it also on 80m and 40m, and whether pattern is an issue.

Truth. However, staying confined to the realm of fact usually carries
with it only the smallest of penalties. I'm not sure the foregoing
discussion stayed as strictly confined.

Source record: 46293

Hi all,

I am looking for a vendor that supplies dipole antennas @2.4Ghz such that the feed extends from the phase center of the antenna.

The reason for this criteria is that I am hoping to measure the wireless link with the antenna element at the receiver at both horizontal and vertical polarizations. It is important for my measurement that I am able to keep the phase center constant for both polarization configurations.

The easiest way I can think to do this is to have a centerfed dipole, fix the feed in position, and then rotate the element around the feed for the orthogonal element. All the dipoles at hypertech where I usually purchase from are end fed.

Any suggestions on a vendor or perhaps an alternative approach for taking such a measurement would be greatly appreciated. Thanks,

Kev

Wis. Selling 100-Foot Fire Lookout Tower
http://abcnews.go.com/US/wireStory?id=2835944

PARK FALLS, Wis. Jan 30, 2007 (AP)&#65533; Talk about a room with a view, this cabin sits 100 feet above the forests of northern Wisconsin and it's on the auction block with a starting price of $1. But there's a catch.

The steel structure that spotters once sat atop to watch for fires has to be moved before it's put to any other use.

"It goes pretty quick. It's like taking apart a set of Tinkertoys," said full-time forest specialist and part-time tower salesman Gary Vander Wyst of the state Department of Natural Resources, when contacted Monday night.

The tower located about seven miles west of Park Falls was erected in the mid 1930s and was one of about 200 fire lookout towers once used to guard the forests of the north.

Bids are to be opened at 11 a.m. Feb. 23 at the Park Falls Ranger Station.

I believe the standard "elbow" (right-angle) antenna that you find screwed into the RPSMA connector on most routers and access points is a center-fed dipole. The reason I believe this is I recently bought an old DWL-900AP+ Access Point at the flea market for $1.00 and when I found it didn't work (who would have guessed that?) I had the pleasure of removing the covers and feasting my eyes on its innards. Inside the case I found the second antenna (of the diversity pair) consisting of two elements: a) the center conductor of the RG-316 cable extended 1.160" from the shield end, and b) a silver plated cylinder 1.0315" long and 0.185" o.d. connected at the shield end, and "folded back down" around the coax feed. Of course the coax feed line runs up its center, and there is a plastic sleeve to keep the feed line centered and spaced away from it.. I believe these two elements make up a half wave dipole, and since the feed line goes up the center of the lower element, it is ideally suited to the simple configuration of the straight-stick antenna. It might look end fed, but I believe it is center fed.

You may be more interested in something that is physically symmetrical about its center, and for that I can only suggest fabricating a dipole from a strip of copperclad PCB stock 2.31" long with a gap cut in the center and the coax feed soldered across the gap. Its width can be anything around

0.10" or so.

Hi All,

I have a couple of late model MFJ roller inductor antenna tuners with the roller on the inside of the inductor. My old 989C with an external roller was smooth as glass. These newer ones with the roller on the inside of the inductor really are rough. They have a knob with a finger hole, but cannot be spun with 1 finger--you have to grab the entire knob to turn it. I have a 989D with a crank type knob that has a slip clutch as part of the knob, and if you try and turn it real slow, the clutch slips instead od the roller progressing slowly.

Has anyone "fixed" this problem with their late model MFJ ???

From: Snoopy@BoiseSt.edu
Message-ID: <DoidnRiueftdl13YnZ2dnUVZ_rXinZ2d@hawaiiantel.net>
Source record: 46299

I recently built a modified vertical dipole
from wire and using a pole and trees as supports.
I had hoped it would work on 2 bands 75 and 40 but it only
works on one 75 where the VSWR is 1.3:1 and the bandwidth is 85 khz
for the 2:1 points.

On 40 meters the VSWR is over 10:1 so I thought I could use a 1/4 coax
matching section 50 ohms but this doesnt solve the problem either as the
VSWR doesnt change much with the extra coax section.

I did cut the section properly as the velocity factor for the coax is .78%
which gave me 26.825 ft.

Not sure what I am doing wrong or assuming - but looks like I could
use some input.

I once measured a 250 mV RMS signal (+1 dBm) at my receiver input when using a vertical antenna, from KGEI, a religious shortwave broadcasting station near San Francisco, about 600 miles from here. It was at night, and KGEI was just above the 40 meter band, 7335 kHz as I recall. They were broadcasting in Russian, so their pattern was probably pretty much in my direction.

I'm quite sure the folks in Europe routinely see signals larger than this from SW broadcast stations.

Unless i am more mistaken than usual, the basic reference distance for
radiated power is 1 meter from the phase center of the antenna. Of course
depending on wavelength / frequency this could mean sub-near field
measurements to normal (semi-far to far field) measurements.

Hi Tom,
well, after few researches on several books, I found that the formula
I provided by me works only for real Z0. The general formula valid in
case Z0 is complex is the follow:

S11=(Zin-Z0*)/(Zin+Z0)

Where Z0* is the conjugate of Z0. Obviously, if Z0 is real, the
conjugate coincide with the real one.
However, thank you for your interest ;-)

Camelot

What do you mean by "modified"? We will need antenna dimensions,
where the feed point is, overall height, height above ground, is it
straight or bent, etc., in order to give you any advice...

The only immediate comment I can make is that any 'dipole' that is
near 50 ohms at the feed point is going to be several thousand ohms at
double the frequency... A matching section of coax will not help...

Time is related to nothing. Time *is*. Sorry Cecil - I read the book
too and it didn't do much for me. That fellow wants to throw away
everything for little - perhaps we should call his methods S'macco razor?

The cesium standard is defined as "in the absence of external
influences. Not a thing at all there that is strange. The meter, that
most arbitrary of measurements, had a standard, the Platinum-Iridium
metre that must be measured at the temperature of melting ice. Measure
it at 1200 degrees, and you'll get a different result.

Nobody denies the existence of the meter.

Oh, heres a good one. Today, the official measurement of the meter is 1,650,763.73 times the wavelength of the emission of Krypton-86 atoms in a vacuum.

Since we usually don't have that lying around the house, they tied it to time and the speed of light.

This tells us that the meter is the length of the path traveled by light in a vacuum during a time interval of 1/299 792 458 second. for us dilettantes, although official measurements must still use the other mode.

So what's all this crap that Coslo's spouting?

Simply this:

It's all arbitrary

Nothing stays the same - Things change because of external forces, Everything changes - If we were Doppler shifted, items that were along with us for the ride would be the same.

Those weird elements were chosen by conditions at the limits of our measurement abilities at the time we settled upon them.

That the elements change under different conditions doesn't negate their use at the proper conditions.

If there was any way to get a low SWR on a simple
single-wire coax-fed dipole on 75m and 40m at the
same time, half of the ham population would have one.

A soon-to-be-published "Worldradio" article of mine
describes a fixed length dipole with a fixed feedline
length that works well on 40m and 75m without an antenna
tuner.

Yes, the Catholic Church felt that the Sun was not at the center of
the universe. What an old fashioned notion. :-)

I'm not sure where you got it, but the formula with the complex conjugate is NOT correct! The formula without complex conjugate is correct, for complex Z and Z0, both.

That the formula using the complex conjugate is incorrect is trivial to see: consider that a line terminated in a load equal to the line's characteristic impedance (be it purely resistive, or complex) has no reflection. That is, if load Z = Z0, there is no reflection. Then if Z0 is complex and has a non-zero reactive component, your formula yields S11 which is not zero, for a line which is terminated to have no reflection. As far as I am concerned, that would be incorrect. The original formula, without complex conjugate, yields the correct answer for this case. Can you come up with a case where it is incorrect?

Cheers,
Tom

The feedpoint impedance of a full wave dipole is likely to be in the
region of 4000 ohms.

A quarter wave transformer needs to be of Zo (50*4000)^0.5 or 447 ohms.
You will not find a practical coax line with such Zo.

If you for instance used a quarter wave of RG58C/U for a transformer, the
input impedance would be 2 ohms (VSWR=25) (taking into account the 5+dB
of loss in the transformer.

Both the length and the Zo of a quarter wave transformer are important to
its operation.

Does this help to explain the results you observed?

looks like the letter "H" on its side "normally" but modified
the feed is asymmertical about 5 ft off the gound.

similar to Force 12 Sigma 80

it looks like this

```
|
|
| abot 56 ft high
|
|
|
|
```

feed here has 2 loading coils

```
|
___________|____________ both sides approx 17 ft
|
```

base insulator here

_|_ base mount

ground

feed point impedance is supposed to be very low - maybe 12 ohms

We will need antenna dimensions,

Which gives rise to the question, where did the match at 75 meters
come from? I suspect it comes from the added loading.

Next question, why does it have the high mismatch for 40 meters. The
same suspicion follows logically (as the harmonic relationships follow
logically).

With loading resonance is not length, it is the combination of all
elements. What appears to be a normal (good) 75 meter operation
should also appear to be normal (poor) 40 meter operation. At 75
meters, the antenna is normally Low-Z. At 40 meters, the antenna is
normally Hi-Z. Your SWR measurement confirms the sense of "normal" in
both bands.

Hi Tom,
as far as I am concerned, your observations are rights only if we are talking about real quantities. If you have a load that is complex then you obtain perfect matching (there is no reflection) only if Z0 is not equal to Zin but it is the conjugate of Zin. If you remember, this is the same condition valid for the maximum power transferring when the load in complex. Do you agree with these considerations?

Regards,

Camelot

Snoopy@BoiseSt.edu wrote:
> maybe I should have asked does my coax tune my antenna???????

When the load impedance is not 50 ohms and the target impedance is 50 ohms, 50 ohm coax cannot tune your antenna system to a 50 ohm match. In fact, using 50 ohm coax with an SWR not equal to 1:1 is one way of guaranteeing that the transmitter will *never* see 50 ohms without some help from a tuner or other matching method. (Extensive losses will also bring the SWR closer to 1:1).

If the target impedance is 50 ohms, only a characteristic impedance different from 50 ohms can transform the non-50 ohm impedance to 50 ohms. And that can only be done when the SWR is not 1:1. Note that in Owen's 1/4WL matching equation, only if the load and source are both 50 ohms does the equation result in Z0 = 50 ohms. Such a system is called a "flat" system with a trivial default SWR of 1:1.

An autotuner at the feedpoint will solve the problem or a parallel feedline with a Z0 of 300-600 ohms will solve the problem. I have solved the problem at my QTH with a 148 foot dipole and 90 feet of 450 ohm ladder-line. That antenna system is simultaneously resonant at my QTH on both 7.15 MHz and 3.8 MHz at the same time. And it is also close to resonance on 17m.

A better description would help. That looks more
like a ground plane antenna than it does a dipole.
Please describe the antenna in more detail.

Hmmm, I can't make much of this diagram and the group has decided to use passive aggressive behavior to "teach you"... You are asking for help and getting didactics thrown in your face... Shame on them!

I doubt you can feed this antenna on 40 with coax... You will need to either put a tuner at the feed point, or resort to open wire line and a tuner at the radio...

My first impulse would be to turn this into a top loaded vertical with an elevated counterpoise, the vertical self resonant on 40 and loaded for 80...
Feed it at the bottom of the vertical section with the braid going to the 17 foot horizontals (some tuning needed)... Use a loading coil about half way up the vertical for 80 and short it out for 40... The counterpoise (the 17 foot horizontals as best I can make out) would be coil loaded at at the center connection of the 2 "radials" so they are resonant on 80 with a shroting clip for 40... A relay will select for you, or you can walk out and manually move the clips...

Go to the library there and get an interloan copy of Moxon's "HF Antennas for all locations"... He has an excellent discussion of loaded radials/counterpoises, etc... With his help you should see how to make your antenna play... Any problems drop me an email through k8do@arrl.org and I will give you a fax number where you can shoot me a diagram of your antenna and we can discuss it...

cheers ... denny / k8do

I didn't know that the Catholic church even knew about atomic clocks at that time, Cecil! Something new to learn every day. 8^)

You slippery sloped from an atomic clock to ancient religion on me.

"in the absence of incontrovertible proof to the contrary, the world was created in the fall of 4004 B.C." ;^)

One of the things that help us in the determination of cosmological age, and all scientific endeavors is that most things end up fitting together pretty well. Atomic decay tends to mesh together with determination of the age of artifacts. It proved itself on items of known age. The concept simply works. That's just one example.

To say that all things have been discovered is naive hubris though. I'm still waiting for evidence of proton decay, without it the Big Bang has a Big Problem. But it doesn't make sense to throw everything we do know away because of that one issue - at least until something better comes along that fits with what we do know.

Let's drop away from cosmology for a moment..

Take say, number 14 bare wire, and make a dipole for some arbitrary frequency. at some arbitrary height.

Raise the antenna and lower the antenna. Do the antenna characteristics stay the same?

Substitute insulated number 14 wire for the bare wire at the same length. Do the characteristics stay the same?

Of course not. The differences are easily measurable, or at least easily modelable.

That isn't religion, it fits in with what we do know about physics. That VF changes depending on the insulating material doesn't mean that the original characteristics are null and void. Just means they have

changed in a manner that is predictable, and for which cause is known.

No Papal Bull required! ;^)

Actually, there is an unexplained time drift between atomic
decay and Bristle Cone Pine rings that can be explained if
seconds are getting shorter.

> That isn't religion, it fits in with what we do know about physics.

And of course, that is in the present space-time. But using
a localized present space-time standard to obtain an absolute
value for something that existed far outside of that present
localized space-time just doesn't "fit". For all we know, the
first half of the existence of the universe consumed all of
one second of space-time as it existed way back then.

What is the length of time that it takes for one entangled
particle to have an affect the other when they are a million
miles apart?

In our High School electronics shop, we had an entire Superhet tube radio demo unit mounted on the wall, with all components pluggable. Seniors and juniors were mixed in the class, and one of the favorite rituals for the older guys was to pull one of the p.s. Electrolytics out very carefully, and toss it to one of the new guys with a "catch it quick" command.

Of course, I never partook of such tomfoolery.

Ahh, you see what we are dealing with, eh Richard?

I also made a reply that hasn't been rejected (yet) but it does deal directly with the problem. It gives an opinion on the likely success of the censored newsgroup, gives an opinion regarding what problems are real problems, then offers a solution that does not required a censored newsgroup. I received two notices that it was pending.

Most interesting that your censored post, while not addressing the issue in excruciating detail, is close enough by any reasonable standard to the subject, simply offering a little comparison at the end.

I enjoy the little side roads we take in our rraa threads, they are what makes the group enjoyable. Sometimes a few members appear to have eaten a little too much red meat, but it all settles down in the end.

At the risk of flattering, I think any newsgroup that wouldn't accept one of your posts is losing more than you are.

Regardless of the excuses given, your post was just lumped in with the whackos that have been polluting the newsgroups the past year or so. Unforgivable.

Perhaps we need a "Too Hot for rec.radio.amateur.moderated" list? ;^)

You do know that the length of Days has changed and continues to change? I sat through a wonderful presentation by a scientist on the changing length of days that he thinks is possible to prove through "microgrowth rings" in fossils. You need very well preserved fossils to look at this, and he presented some pretty compelling evidence, but stopped short of saying "this is how it is" Scientists - go figure! ;^)

True, but we shouldn't go so far as to infer that 1 Hz might sometimes
have more or less than one cycle in a second - no matter how much
different each second might be from the next.

We often infer that a frequency has lessened due to
the red shift which could certainly be a shortening
of a second from the time the light was generated
until now.

OK, it is easy to see that a perfect match is NOT the conjugate, but an impedance equal to the line's Z0. Consider an "infinitely long" line. You know that the input impedance equals Z0 for all time, and there can be no reflection. Whatever you send out just keeps going.

Now think about that line as two pieces, connected together. The first piece is, say, 100 meters long, connected on one end to the signal generator, and on the other end to the remaining piece of line, still infinitely long. Now you have connected a load of Z0 (the infinitely long piece) to a 100 meter section of line with characteristic impedance Z0, and clearly there are no reflections where the lines are connected together.

It should be clear that you can just as well replace the infinite section of line with a load equal to Z0 (NOT equal to the conjugate of Z0, if Z0 has a reactive part), and there will be no change in the conditions in the 100 meter section between the Z0 load and the signal generator.

You can arrive at EXACTLY the same conclusion if you consider the current and voltage in a "forward" wave (including their phase relationship) and the current and voltage in a load equal to Z0, and the current and voltage in a load equal to the complex conjugate of Z0. You will see that for a line of impedance Z0, only a load equal to Z0 will have the correct voltage and current at its terminals to match only a forward wave on the line, and thus allow for zero reflected wave.

It is a separate, but related, issue to discuss exactly what the matching should be to get the most power from a generator to a load through a section of such line. But it should be clear that to have zero reflection, zero S11, the load must equal Z0 and in general not Z0* (though of course Z0=Z0* if Z0 is purely resistive).

Cheers,
Tom

Right. Seemed logical to me to deduce that the number of seconds in a year might have changed, but to infer from that that the length of the second has changed seems like quite a leap to me. Given the number of perturbations in the system, it's more likely the length of our path around the Sun has changed slightly over time. But hey, I'm no biologist.

The phenomenon of red shift is readily observable - that's how it was discovered. Line spectra from known elements is observed to be shifted in wavelength down from where it appears in the rest frame. The cause could be doppler shifting due to relative motion, or some other reason. If the length of the second were different, then so would be the speed of light as well as the constant of proportionality between frequency and wavelength at the source. In fact all kinds of physics would have to be different. There is certainly a probability for either case. Whether the probabilities are of the same magnitude is debatable.

To see why that is false, refer to Lorentz's
transformation for time at a velocity near
the speed of light. Time can vary all over
the universe while the speed of light remains
constant (at least by definition :-). Since
time is one dimension for the speed of light,
the problem is self-correcting.

If tomorrow's second were 1/2 half of today's
second, nobody would even notice.

If someone used a cesium clock near a black
hole to come up with a "standard" second, it
would be nowhere near the same length of time
as a cesium clock on Earth. Time passes very
slowly near the event horizon of a black hole
but light keeps on trucking at the speed of
light.

If the second were "smaller", then light could obviously no longer travel 3x10^8 of our meters in one of them. Try not to lose track of the reference frame, Cecil. (Remember, it's the one in which the red shift is being measured).

Of what, exactly? So a new group is planned that will be moderated. Big deal. The other groups are still wide open for anyone to post. I don't see the reason for alarm.

the physical antenna stays as is and works extremely well on 75.
What has me asking the questions is that I was told a 1/4 wave piece of coax
would get it to work on 40.

Maybe I need to run it thru some modeling software and see what actually
does need to happen to get 40 to work.

go to Force 12 website and check out the sigma 80

this is similar in that instead of having horizontal elements on the top its straight vertical.

signal reports on 80 have been very impressive.

Hi Nate,

You confuse our amusement of impotent autocracy with alarm? Or are
you speaking of the very little effort required to alarm the school
hall monitors?

I visited the group to observe the response to my first reaction.
Basically their position is that taking responsibility for yourself
with your own killfile management is a task too great for the mass of
humanity. In clearer terms, the moderators have a very low opinion of
those they "protect." The veneer of respectability flaked off the
surface quite quickly.

The sand-bagged "proposal" comes with only one acceptable solution,
the justification for their thread of 120-odd follow-on responses
(white noise chatter) doesn't change that one iota. It was obvious my
solution's rejection was waiting in the wings like a coup de gras.

[Actually it is coup de grï¿½ce, pronounced grahs. Most americans
pronounce gras as grah. The difference is coup de grï¿½ce is the
killing blow for the grace of a quick death. A coup de gras is a blow
of fat - certainly more accurately rendered there (pun intended). If
I am to merit expulsion for rhetorically tweaking a nose, I may as
well murder them with panache.]

> >

Hello, and I don't know where you obtained that formula but it's
incorrect. S11 in terms of a reflection coefficient is given by your
formula above but without the complex conjugate of Z0. I have seen
reflection coefficients in technical journals defined with a complex
conjugate Z0 as you have shown but that's not consistent with scattering
or transmission line theory (unless Z0 is real). I know it seems
counterintuitve but a source of complex Z0 would be matched (no
voltage/current reflections) to a transmission line having the same
characteristic impedance. This condition does not in general correspond
to the condition of maximum power transfer from source to line.
Conversely a line of complex Z0 impedance connected to a source of complex
Z0* impedance represents maximum power transfer from source to line but we
still have voltage and current "reflections" RELATIVE to Z0. What you
have to keep in mind is that incident (forward) and reflected
voltages/currents only have meaning when they are referenced to an
impedance, say Z0. And to monitor steady-state incident and reflected
waves you need to separate the steady-state voltage (or current) into
these components using a bridge or directional coupler (sampling devices
that are also designed to use Z0 (e.g. 50 + j0 ohms) as a reference).

In most applications what I've said is moot since line impedance is
usually real or very close to real and we are dealing with sources having
real or very close to real impedances. Under these conditions the matched
condition coincides with maximum power transfer.

If you want an in-depth treatment of what I've attempted to summarize I
recommend the chapter on circuit analysis in the "Electronic Designers'
Handbook", ed. E.J. Giacoletto, published by McGraw-Hill. Sincerely,

It is the frequency that is red-shifted, not the
velocity. A shorter second results in a lower
frequency. Relativity won't allow the velocity
of light to change but everything else changes
including meters and seconds.

Richard, I am not trying to be an ass here, but I was told BEFORE the antenna was built it would work on 40.
So it got built and doesnt work on 40 as is. It was suggested at the time to use a 1/4 wave section of coax to get it to work on 40, which as you know it doesnt.

All I want to do is figure out a way to get it to work on 40 now.

Believe me this antenna works extremely well on 80. 20 over 9 reports from ZL when the VK's there are only 10 over 9.

This configuration works well, I am sure someone could build a similar version just for 40 and be a big gun on 40.

The reason for their alarm is they know people will go to the Moderated
group to get away from their
crap they are posting, thus they then wont have anyone left to hear their
drivel. The self imposed
importance thus will go away and they will be once again left to what they
really are.

A shorted 1/4WL 80m parallel stub will yield a
high impedance on 80m and a low impedance on 40m.
This is sometimes used with open-wire line to
achieve a match on both bands for a dipole that
is 1/2WL on 80m and 1WL on 40m. Also to open up
a 1WL 40m loop for use on 80m as a 1/2WL dipole.

Quantum mechanics does however:

http://science.nasa.gov/headlines/y2002/27mar_stoplight.htm

On a more humble level, Light changes speed as it passes through
different mediums, such as water.

To amplify just a bit on what John wrote, it's convenient to express the S-parameters referenced to an impedance that's accepted by other people you want to exchange data with, so that they don't have to transform your data to match their reference. 50 ohms resistive is pretty universally accepted in the non-television RF industry. Bear in mind that the S parameters work just fine, even though the transmission lines you are working with may not be exactly 50 ohms resistive, or even close to 50 ohms. In such a case, of course, S11 will not have the same meaning as a reflection coefficient for that line.

Part of the "universally accepted" aspect is that the vast majority of RF test equipment is built to take readings referenced to 50 ohms resistive. We take great care to make sure that things look as close to 50+j0 as practical, over a wide frequency range. That said, there are particular industries where other impedances are used. 75 ohms is used in the video and television industry more commonly than 50 ohms, and you can buy vector network analyzers whose native impedance is 75 ohms. We've also made equipment to match the "standard" reference impedances used by telephone services and the audio industry.

Finally, to head off the nearly inevitable rant that (Z-Z0)/(Z+Z0), for a complex Z0, allows S11 to have a magnitude greater than unity for a passive load, yes, we know that's true, and it's really NOT a problem. Don't try to attach more physical significance to the reflection coefficient than is actually there.

(John, I do rather wish you'd dropped the line at the beginning of your post that said I had written the short segment you quoted from my posting, since I didn't write any of it; it was only lines I'd quoted from the original by "camelot"...but I trust that will be fairly obvious to readers.)

Cheers,
Tom

Lets take your postings here, Nate.

Richard and myself were making comments on his rejected post, and finding some humor in the whole process. Moderation has a certain inherent humor.

You apparently believe that our posts are somehow sour grapes, or simple bitterness. Perhaps if this were a moderated group, and you were the moderator, you would censor our posts.

No, Nate, what I find incredibly amusing might be displayed for all by the simple task of googling up rrap for the last couple years. What prompted the censored newgsroup (no Newspeak here, my good man!) is that filth. Which eventually spread over all the rra groups.

Fast forward to the present, and we see an example of comparative posting. Richards erudite, if sometimes acerbic, but always entertaining posts are apparently held in the same contempt as the filth spewed by a group of challenged folk.

And that is humor in the vein of "Look out what you ask for - you just might get it".

I could care less about the moderated group. I suspect that after an initial flurry of interest, many users will drift away.

I take care of my own self in the newsgroups, thankyouverymuch. I wonder about people who have to have a censor take care of them. I find them funny too.

You are a victim of poor information. That is evident in the false assurance (it simply doesn't make sense) and the positive proof of your measurements.

>So it got built and doesnt work on 40 as is.

No one here is surprised by that outcome.

>It was suggested at the time to
>use a 1/4 wave section of coax to get it to work on 40, which as you know
>it doesnt.

A quarter wave solution was offered by Owen which was the correct solution. This does not mean it would turn a dog into a performer, it simply meant it would match. Now, as to the matter of making it match using coax, THAT is a hash pipe dream. You may eventually succeed through luck and happenstance, but chances are that coax will glow at night.

>All I want to do is figure out a way to get it to work on 40 now.

As I offered, Owen has already done the work, but only you can build it and discover it works.

>Believe me this antenna works extremely well on 80. 20 over 9 reports from
>ZL when the VK's there are only 10 over 9.

That's nice, but it doesn't solve 40M.

Two amazing things about this:
1. It's taken 25 years to figure it out;
2. It hasn't happened yet;
3. They have to ask permission to see if it sounds like a good idea?

This is second in competency only to the Department of Homeland
Security: "All Katrina victims, assemble for your safety at the Sport
Coliseum. Busses, food, and water will arrive someday. Excuse the
bathrooms that are out of order and use the hallway."

Actually I encourage the development of a moderated group, they
deserve it. I can imagine some of our erstwhile visitors moving there

Hello All,

I have just gotten my tech license and am eager to get my station up and running. I am starting on a shoestring; currently, I have no equipment whatsoever and don't know what I should buy just yet. In absence of a rig, I am now studying to pass my General license exam next month.

I am very interested in building my own HF/VHF/UHF antennas. I've seen the ARRL books, but I was hoping that you good folks might have some favorite websites, book titles or magazine issues [old or new] that you'd be willing to pass along that could get me started.

Many thanks for taking the time to respond!

73's to you all!

Hi Alain,

You can certainly buy more books than there are antennas, but really,
the ARRL manual (any one of them) is enough to make your first foray.
This will make it easier to ask questions, and to focus on specific
needs instead of shotgunning what is available.

The best advice is to remark that all antenna designs can be scaled to
any other frequency. The building details are the sticky part.

As the person who was once accused of being the "nicest person in
rrap". I can say

Wrongo!

Find out who is posting what before you go accusing people. Perhaps
accuracy is not important to you, In which case rram might just have an
opening.

In a way, the answer is "yes". If the length of a second
is inviolate, then the speed-of-light is not a constant
since those are contradictory concepts.

A system of physics could have been based on an "absolute
objective second" of time, but it results in a total package
with a lot of problems as yet unsolved. An absolute velocity
of light in a vacuum seems to solve a lot of those problems
but results in length being a variable and time being a
variable while length and time are the dimensions of velocity.

Personally, I think everything is a variable and therefore,
there are no constants, except of course, for your constant
kibitzing. :-)

Hmm, research reveals nothing of your having said anything about
Einstein's death. Nothing about his being responsible for the speed
of light, and certainly nothing about his being responsible for
slowing time down.

Instead of making bland exclamations, can you actually offer us facts
that Einstein is responsible for both setting the speed of light AND
time slowing down? This God-like quality that you have invested in
him and then taken some of it away with the equivocation of
> In a way, the answer is "yes".
doesn't really say anything does it?

The world waits in wonder at your assertion of Einstein's ability to
set the speed of light and time - especially when it had been
investigated and quantified by many earlier workers, notably Michelson
and Morely.

1061. help- Mobile 10meters on a jeep

Source record: 46225

I have been advised by some hams that the best way I can hope to do 10-meters on my jeep is to mount my antenna ON THE WINDSHIELD to get a good ground plane. I read somewhere since then that the primary reason for cophasing CB antennas on trucks is NOT to direct the gain front and back, but to even the ground plane as though the antenna were in the center of the truck. Could I achieve the same effect with my Jeep by cophasing antennas on either side of the jeep by the doors? Even better- could I do this diagonally across from one corner of my jeep to the other? I heard the further apart the antennas are, the better, and I'm not really trying to get front/back gain for DXing.

Hi All,

Well it stands to reason there is nothing to be said in this regard

On Fri, 02 Feb 2007 18:40:10 GMT, Cecil Moore <mycall@hotmail.com>
wrote:
>One thing had to be nailed down and Einstein chose the speed of light.

as Einstein was never responsible for any such thing.

Fact of the matter was previous to Michelson and Morely's work, a
Scottish fellow by the name of Maxwell had already DEFINED the speed
of light. Michelson and Morely merely confirmed it in the absence of
a disturbing ï¿½ther. Their confirmation merely extended the
experimental resolution of a quantity already known.

Instead, Einstein took Maxwell's DEFINED speed of light, and observed
that it would be constant in any Inertial Frame of Reference. This
means that the same beam of light (whose source or origin is
immaterial) is measured in a fixed frame (nonsense of course, but this
is Einstein's thought experiment), it will be equally determined by a
moving frame.

>Did I get the commas correct Richard?

No.

Commas can be used to clear cloudy sentences. You did that in the
first sentence, but you also had the suggestion of a comma splice
later. Proper usage would have been to replace it with a semicolon,
or eliminate it (break the splice) to make another sentence. However
the second sentence is not a sentence, much less two of them. There
is no predicate. So discussion of proper comma usage is largely moot.

I am sure most followed the thoughts through to completion without a
blip in understanding. English is quite flexible in that regard.

Well, I knew it was botched up, since I botched it intentionally, which
is why I asked. I was sure that you would have an answer worth reading. ;)

I am curious as to why I seldom see my own posts, and even then only
after a long delay, while I get most others almost immediately.
Obviously my post showed on your news server within minutes of my
sending it. I still haven't seen it here.

Last year the roller inductor on my 989C became a little bit dirty and
needed extensive cleaning after using it for several years at 1KW. I cleaned
it up but it was not easy. MFJ recommended that the only lubrication I
should use is pure graphite powder which I found available at the local ACE
hardware. It looks like it should be cleaned every year or so. That 989C
roller inductor is a work of art and MFJ sells replacements for about
$60.00. If I had a 989D I would probably buy a replacement 989C inductor.
When I checked other companies for their prices of roller inductors of
similar size/inductance/turns, they seemed to go for around $280.00, which
probably explains the EC for 989D.

Please Google "relativity" and "Lorentz transforms"
for the technical facts as presented by Einstein.

I never said or implied that Einstein "DEFINED the speed
of light", only that he "nailed it down" in his equations
as the one universal constant - while all other parameters
are subject to relativity effects.

Hi Tom,

Commas are a recent invention for language and quotation marks even
more modern. One writer, outraged by his publisher's demand that he
use punctuation put them all at the end of his book and invited
readers to draw from them and season his words as they pleased.

>I am curious as to why I seldom see my own posts, and even then only

NNTP feeds are a strange thing. I'm surprised that it works. There
have been years when I had to wait quite long to see my own posts. I
am also surprised how computers can flip their bits a billion times a
second, and manage to not get lost (so often).

Let's face it, you never really say anything in the end. We can see
this in the guff like that above. "nailed it down," now there's a
charming non-sequitur. Maxwell preceded him by decades with the
definition of the speed of light - Einstein certainly nailed nothing
there. Maxwell's equations are nothing if not universally applicable,
Einstein didn't add anything that pounded any nail there either. And
to hail-Mary it with
>while all other parameters
>are subject to relativity effects.
contradicts Einstein explicitly in that he taught that "all laws of
physics are the same within all inertial frames of reference."
Einstein did not exclude anything.

Einstein was the first to nail down the speed of light
in free space as an absolute in his relativity equations.
You can verify that fact by Googling "relativity".

What I did was purchase a 1/2 wave 11 meter whip from Radio shack and
trimmed it for 10m. Of course, for 1/2 wave you need not have a ground
plane, only a good ground point. I mounted it on the back bumper. It worked
very well on my Warngler.

Wow, that is some excellent information I didn't know.. that a 1/2
wave antenna doesn't need a ground plane. I looked it up and sure
enough, you're right! However, I'm sad to say that I really doubt
Radio Shack sells a 1/2 wavelength antenna for either 10 or 11
meters. The classic 102" whip, as I understand, is a 1/4 wavelength.
For a second I even considered putting a 2.5-meter (16.4 ft) whip on
my jeep, but I finally decided that really isn't practical. So, any
opinions on the cophasing of two 1/4 waves?

You are right of course...sorry...I didn't caculate the wavelength and was
merely making statements comparing the shorter "loaded" whip (forgetting it
was loaded), concluding the longer whip was 1/2 wave . However, I knew it
was 1/4 wave GP at the time and sometimes I just get afflicted with
oldtimers didease, complicated to exposure of high EM fields. :-)) The
unloaded 1/4 whip still worked well using the frame as a ground plane.

Hi Jim,

You are treading on Cecil's toes in this dance. Soon we may have to
reveal the Lorentzian transformation.

It was Lorentz that described time dilation (using the speed of light)
in 1887 and formalized in 1899, and it was Poincarï¿½ who introduced
this math in 1905, not Einstein.
>>he "nailed it down" in his equations
is an slur on Maxwell, Lamor, Lorentz, and Poincarï¿½'s contributions
that predate Einstein by decades.

But I am not surprised. Lorentzian transformations are alluded to
here in this forum in recent speculations; and they are thoroughly
botched because so few are even vaguely familiar with his work.

Cecil, your habit of hugging the corpses of intellectuals does not
raise your IQ.

Good explanation.

You might add that this applies to coaxial libes whose fields do not
interact. For open wire line the picture is considerably different
because the eleccctric and magnetic fields overlap.

Good explanation.

I would like to add that this applies to coaxial cables only because the fields of the individual lines do not interact.

For parallel lines the situation is quite different due to the overlapping fields and much more difficult to calculate.

The calculation described rlate to a broad band impedance transformer that can easliy be made with coax. The coaxes are connected in parallel on one end and in series on the other. This yields a transformer from 25 ohms unbalanced to 100 ohms balance in the case of 50 ohm line.

It is necessary to make the impedance high for the currents that will flow on the shields. There are two ways to accomplish this. One is to wind the lines onto a ferrite core. The other is to coil the lines to form an air core inductor. The latter is the best approach for high power coax which is a bit big to wind on a core. Also it eliminates any issues of core heating and saturation effects.

I have a GMC pickup with a three magnet magmount on top
of the cab and I use Hamsticks for 20m-10m. There's hardly
any noticeable difference when I move that magmount to
the hood of the pickup. Why not use a three magnet mag-
mount on your Jeep hood with a 10m Hamstick?

Do you have a roll bar on the Jeep? Lots of Jeep drivers
mount their CB antennas in the middle of the roll bar.

No you don't. The stub is a high impedance on 80m in
parallel with a low feedpoint impedance and therefore
has a negligible effect on 80m. It can be left in the
circuit.

The stub is a low impedance on 40m in parallel with
a high feedpoint impedance which lowers the SWR and
makes your transmitter happy. On 40m, the stub acts
as a low impedance load that eventually delivers most
of its stored energy to the high impedance antenna
(assuming the stub is made from low-loss transmission
line).

It was Einstein who first recognized that the Lorentz
transforms actually applied to reality and were not
just another useful set of purely mathematical
transforms. If Lorentz and Poincare had recognized
that fact, they would have gotten credit for the
theory of relativity but guess who got the credit?
Hint: The guy who nailed down the speed of light as
an absolute in his relativity equations. Nowhere have
I ever read that the mathematicians, Lorentz or Poincare,
ever suspected that the speed of light in a vacuum was
a fixed absolute. That concept was left to a physicist.

>>> he "nailed it down" in his equations

> is an slur on Maxwell, Lamor, Lorentz, and Poincarï¿½'s contributions
> that predate Einstein by decades.

No slur intended or implied so it must be a mistaken
inference on your part. You obviously jumped to a wrong
conclusion and do not understand what I meant by "nailed
it down". If everything is relative, then nothing is
fixed. By declaring the speed of light in a vacuum to be
a fixed absolute, Einstein nailed down the cornerstone
of his theory. Relativity needed a reference nailed down.
Einstein nailed down the speed of light as that reference.
In my context, "set it in concrete" would be synonym for
"nailed it down". I do believe the speed of light in a
vacuum is set in concrete within the theory of relativity.

You are walking around a vacant lot and find a rope. You
want to experiment with waves using the rope. You "nail
down" one end of the rope and apply energy at the other
end. Are you slurring the inventors and/or manufacturers
of the rope? Please explain how.

1085. Advice for 75m Mobile Field Strength measurements

Newsgroup: rec.radio.amateur.antenna
Date: 2007-02-03 13:24:08 UTC
From: k1drw <k1drw@comcast.net>
Message-ID: <1170509048.239078.207990@a34g2000cwb.googlegroups.com>
Source record: 46249

Hello:
I am looking words of advice on conducting an informal exercise to evaluate performance of 75m mobile systems. I have done much reading of rec.radio.amateur.antenna threads and have learned much from Cecil, Reg, Keith, Roy, et al. The msg threads addressing how measurements were taken during past shootouts have been very helpful but equipment used in those events seem to be beyond my capabilities.

I am part of an ARES/RACES HF Mobile team. We are in the early stages of assembling our team and have conducted a couple of field exercises. I believe I adequately understand many of the issues related to operating 75m mobile and have concluded (from assessing our mobile configurations) that our systems are VERY compromised. As we conduct our EmComm field exercises we take the opportunity to experiment and make system adjustments that clearly improve performance. Primarily we are using 100w mobile hf rigs with 75m Hamsticks or Hustler resonators. We understand that the vehicle, the antenna, the ground, etc comprise the "System". One important note is that we are not focused on achieving DX communications. Our field of operations is primarily Groundwave within a tri-county area in Eastern Pa (many 600-700 ft ridges and valleys, heavily forrested), perhaps 100 miles max. We do use and experiment with NVIS (using restricted space configurations: tilted whip, Hamstick dipoles, etc) however, this query is relative to Groundwave.

I would like to add an occassional field exercise expressly for the purpose of measuring the performance of our systems (for improvement and detecting problems). We currently have no equipment for this purpose. One device I see advertised and would like some feedback on, is the MFJ-802 Field Strength Meter.

- Would the MFJ-802 be an adequate measuring device for our use ? Any caveats ?
- What test FIELD environment should we try to arrange (e.g. large empty parking lot, or a rural open field) ?
- When testing each vehicle, what space should separate it from other vehicles waiting to be tested ?
- Should the vehicle sit stationery, or be moving in a circle ?

Any suggestions offerred to assist with this effort will be sincerely appreciated.

regards,
Dennis, K1DRW

I don't understand that, Cecil. Yes, the stub will be a halfwave on 40m,
and therefore add a low impedance in parallel with the antenna
feedpoint. Depending on the exact resonant length of the stub, the
impedance will be either a very low value resistor, a low value
inductor, or a large value capacitor. None of these is going to help to
convert the resistive part of the input impedance of the antenna to
something around 50 ohms.

However, I suspect that what the matching arrangement actually consists
of a stub which is connected across the feeder AT SOME DISTANCE from the
antenna feedpoint. If the antenna feedpoint presents a high impedance on
40m, there will be a point at some distance (less than a quarterwave)
back along the feeder (towards the TX) where the resistive part of the
impedance (at that point) is 50 ohm, in parallel with a considerable
capacitive reactance. By choosing the correct length of stub and the
correct distance between the connection of the stub and the antenna
feedpoint, you can probably get a 'reasonable' match for both 80m and
40m.

If this IS the actual physical arrangement, it's time to get the Smith
Charts out!

Ian.

Palomar manufactured a PFS-1 Field Strength Meter
for awhile. You might be able to find a used one.
It works very well in the absence of other strong
signals.

But you can take advantage of what is known already.
A 75m hamstick is 12 dB down from a good center-
loaded bugcatcher or screwdriver. That's at least
2 S-units and maybe more. Hustler systems are 8 dB
down, more than one S-unit. One S-unit can make or
break an emergency communications.

Anyone serious about 75m emergency communications
should replace those dummy loads (hamsticks) with a
real antennas. :-) A well-designed, well-installed
bugcatcher or screwdriver system is hard to beat
on 75m.

Here's my 75m mobile antenna guaranteed to beat
the socks off of a hamstick:

http://www.w5dxp.com/mobscrew.jpg

It is a High Sierra HS-1600 with the optional RV
bottom section. It has a top hat with eight radials
two feet above the coil. The top hat is at a
height of about 10.5 feet above the ground. Watch
out for trees.

You're right, Ian. I was trying to apply the same
principles that causes the stub to turn a full-wave
40m loop into a 1/2WL 75m dipole and had a senior
moment. But that idea would work with RG-174. With
a 3 dB loss in the stub, the impedance looking into
the stub would be around 50 ohms. :-)

What I am lacking is the feedpoint impedance on 40m.
I'll try to get time to model the antenna.

Almost any FS meter can be used as long as it's not overloaded and
saturated to a full peg reading on everything..
Also a distant receiver is ok as long as the signal is stable. Ground
wave is
usually pretty stable if you test quickly.

> - What test FIELD environment should we try to arrange (e.g. large
> empty parking lot, or a rural open field) ?

Doesn't matter, except I would use the same exact spot for every rig
tested. The only thing moving from field to lot, would effect the
ground
quality. The cdx of the ground doesn't really matter as long as each
rig is tested from the same spot. Improvement of the ground would
effect
all rigs equally.

> - When testing each vehicle, what space should separate it from other
> vehicles waiting to be tested ?

I would move and park each one in the same exact spot if I wanted
to be fairly accurate. Ground cdx could possibly change a few feet
away.
Or maybe not, but if I'm doing a test, I want things as equal as
possible.

> - Should the vehicle sit stationery, or be moving in a circle ?

I would sit it still. You are not measuring pattern. Just efficiency.
Any improvement in effeciency will effect all angles or directions
equally. No point in moving around, and could in fact degrade the test
if the ground changes under the vehicle.

I took a look at the Force 12 Sigma-80 and Sigma-40.
Nowhere do they say a Sigma-80 will work on 40m.

The Sigma antennas appear to be center-loaded vertical
dipoles with end hats as in the following fixed font.
FP is the feedpoint.

```
| |
| coil coil |
+-------------/////FP/////-------------+
| || |
| || |
```

I estimated the dimensions of the Sigma-80 from pictures
on the Force 12 web page. The center section is about
36 feet long and the end caps are about 22 feet long.
Plugging those values into EZNEC says that simply
shorting out the loading coils will make the antenna
resonant very close to 40m.

Some elementary books have some strange explanations, this is because they are trying to explain something to someone who probably doesnt have the proper background yet.They are well meaning and are a great help at getting the novice on the air. One such mistake is calling a 4 ft long antenna that has a coil to make it resonate on the 10M band a "10M loaded 1/4 wavelength antenna" . Actually this would be an 1/8 wl antenna more or less. So watch out

Jimmie

That's it then.
Connect a 80m quarterwave S/C stub (preferably twin feeder) across both coils (ie from the outer end to the outer end). That will leave the coils O/C on 80m and S/C the coils on 40m.
Should work!
Ian.

One thing I would do is get a portable antennna, maybe one of those 30+ft fiberglass whips. Tried one of thes several years ago and could fairly reliably talk from Charlotte NC to Atlanta Ga using a freq near the 40M band. An antenna like this can be setup in just a few minutes. The antenna we used broke down into sections about 4 ft long so its something you could keep in the trunk of a sedan.

Jimmie

A somewhat weird looking modification for a center-fed
vertical antenna. I suppose the two stubs could double
as guy wires. I might be tempted to accomplish the switching
with a large open frame relay or two.

When I had my CJ I had a CB antenna mounted on a ball mount back behind the
rear wheel well.

They should be more careful and specify that they are
talking about electrical lengths, not physical lengths.

For instance, the following stub is electrically 90
degrees long even though it is physically only 38
degrees long.

1/4WL stub
------------------+--------
27 deg, Z0=500 11 deg, Z0=50

Incidentally, this is how a loaded antenna can be
90 degrees long electrically while being physically
much shorter than 90 degrees.

From the original ASCII diagram, it isn't too clear what the
configuration is. Is it actually a 'single-ended' vertical version of
your diagram above of the horizontal balanced antenna? The two loading
coils (original diagram) would in series on 80m, with the stub shorting
out the lower one on 40m. This would enable freer adjustments of the
resonances of the antenna on the two bands. It would also help explain
the original description that the stub was connected 'across the
feedpoint' (although it isn't).

If the roll bar is thick enough, you can drill and tap it to mount the whip directly. Then use a gamma match so you don't have to worry about insulating the mount.

Hi Dennis,

Only that its purchase may be to lend the appearance of credibility beyond the instrument's capacity to deliver it. This instrument, as it should be, is dirt-simple to construct; and for your purposes should have a digital readout. You can achieve the same thing by using a DVM connected to the meter's terminals, but by that time you could as easily build a detector box with DVM pin jacks and an antenna connector.

>- What test FIELD environment should we try to arrange (e.g. large
>empty parking lot, or a rural open field) ?

As others point out, consistency in testing is paramount. All those tested will suffer/benefit equally under same conditions.

>- When testing each vehicle, what space should separate it from other
>vehicles waiting to be tested ?

Where do you want to aim the signal? Think about it, you have an array of antennas, one driven and the rest parasitic and parked nearby. Does this remind you of something? Does spacing and proximity count? Same admonition applies if you have the test group near your detector antenna.

Think in terms of wavelength. Stay out of near fields.

>- Should the vehicle sit stationery, or be moving in a circle ?

As long as you are as far away so as to not perceive the shift in signal strength on the basis of path length variation. Is a 30 foot turning radius tested 300 feet away going to matter? Terrain may have some bearing here.

A dry run is encouraged.

If you really want to get yourself a better antenna, you should look
at a Ballon Elevated Longwire, and use your Portable MF/HF Stations to
connect VHF/UHF Mobile Stations together in a network, to cover your
Service Area. Mobile MF/HF from vehicals is ALWAYS going to have a
compromised antenna, and VHF/UHF Mobiles and Handhelds are significantly
less powerhungry, and can cover large chunks of country, and report
back to a centrally located, designated High Point Elevated MF/HF
Portable Station, where antennas with less compromised parameters
can be employed, to communicate between local VHF/UHF Groups.
This approch isn't Rocket Science, and has been well thought out for
such purposes, by folks that design Comm's Systems to actually work.....

As I understand it, the antenna under discussion is like
the Sigma-80 except the top hat is omitted and the upper
element is instead extended upward - like this.

```
|
coil coil |
---------------------/////FP/////-------------+
|| |
|| |
```

So I'm assuming whatever works for the Sigma-80
will work for this antenna.

Thanks for all the ideas guys. I'm still really interested in the
cophasing thing. I have mounted a CB whip on the roll bar before, but
it has two disadvantages: Extreme height of the antenna and the
inability to close the soft top while the antenna's up. Could I not
cophase diagonally and therefore center the patten ?

First a few thoughts. Co-phasing doubles the cost of
the antenna without outperforming a single whip (unless
the elements are separated by 1/4WL or more). So
why not a magmount on the hood with a single whip?
That would be my solution but I'm not very "cool". :-)
My contacts could not tell the difference between the
magmount on the roof of my pickup Vs on my hood.

Phasing would work best front-to-back. With 135 degree
phasing in elements separated by 1/8WL, a whopping 4 dB
gain is possible switchable from front to back. If 1/4WL
spacing is possible, bidirectional front and back gain
of 3.5 dB is possible with 180 degree phasing. If I were
driving an 18 wheeler, this is what I would do. Changing
the phasing to 90 degrees would give me a front or back
vertical beam.

There's no reason why your co-phasing idea will not work.
The feedpoint impedance of the two elements in parallel
will be 1/2 of the impedance of each element transformed
by the length of coax chosen. If you put the coax 'T' 1/4WL
back from each element, the impedance at that point should
be close to the feedpoint impedance of each element (assuming
35 ohms).

If the option is available to you, consider choosing a meter with an external antenna connected through a coax connector. By placing a calibrated attenuator between the antenna and the meter, you can readily obtain resolution and repeatability approaching 1 dB. When coupled with a DMM, as Richard Clark suggested, you will have very effective instrumentation.

If you rely instead only on the meter dial, most likely calibrated in volts, your measurements will be affected by circuit and meter nonlinearities and the need to convert voltage readings into dB.

Good luck,

Chuck

Excellent.. If I put my antennas on opposite corners of the Jeep as I was thinking, I find that they will be 4.2 meters apart. I promise to go home and see what the ARRL handbook says about cophasing, but I only understood what you just told me partially. Are you describing a way to get better front/back gain from a system with one antenna in front and one in back, as opposed to the conventional "trucker" setup? I have no particular use for directional gain on 10 meters, by the way.

I know a lot of people are reluctant to do the superior front-to-back cophasing because it looks goofy, but I can assure I'm not interested in being "cool" either! I want the most efficient 10-m operation I can get out of a Jeep Wrangler.

Hey congrads Joe -- way to go. You now have full band privileges -- lots of DX lurking in the extra band.

CL

1115. On 144MHz J-Pole vs EDZ - Some mad ramblings.

Newsgroup: rec.radio.amateur.antenna
Date: 2007-02-04 00:29:41 UTC
From: Bob Bob <bob3bob3@suddenlink.net>
Message-ID: <m0mf94-qms.ln1@p400bob.personal.cox.net>
Source record: 46129

Hi NG

I am in the throes of building an omni for 2m and am trying to decide between a "super jpole" and an extended double zepp. I have more or less gone for 5/8 over 5/8 radiators with a center "hairpin" phasing section.

The J-Pole is of course fed through the usual "hairpin" arrangement at the bottom of the antenna. The EDZ at the center phasing/hairpin section.

Okay so here are the questions/thoughts.

- I don't mind mind mounting on the side of the mast. The whole thing will eventually be rotatable and the mast itself might be a useful reflector for a few more dB of fwd gain. This also makes the EDZ reasonably easy to feed.

- I know of the issues with radiating feedline and pattern lifting for the jpole. Wondering if a 4:1 coaxial balun would resolve this and also give a wider VSWR bandwidth?

- I also note the J-Pole hairpin/matching section is never quite balanced as the load Z at the connected vs non connected ends skews it some. (From cebik) To my mind this has two thoughts, is it worth skewing the feed point (eg one side of the feedpoint 1/2" below the other) and does (static/lighting) grounding the supposed electrically neutral point affect the efficiency/pattern of the thing.

- Wondering if feeding from one end results in ohmic losses reducing the radiation from the upper element. Thus skewing the pattern undesirably upwards. I heard this use to be a big problem with early UHF coaxial collinear antennas. Mounting upside down was supposedly a good fix!

- I had thought for ages that skying radiation from ground effects is actually a function of the amount of radiation that goes at a downwards angle. (ie a perfect antenna is one that doesn't radiate below the "horizon" in free space) If one uses a 5/8 element for the antenna's mentioned above the normal high lobe one gets might contribute to this problem. In other words is it better to (say) use 3x1/2 wave rather than 2x5/8 wave elements in either an EDZ or JPole setup. (I'll be modeling this for my own interest but would appreciate feedback)

- This of course begs the question as to whether one should even be concerned about ground reflection on 2m with a 30ft mast!

This topic can of course be very exhausting. In my case though it is more to decide which device to build.

Tnxs for any thoughts and ideas.

>give a wider VSWR bandwidth?

Hi Bobï¿½,

Nope. The width is determined by Q. Pattern is determined by
physical vs. electrical size. Neither of those is dependent on a
BalUn. Now a BalUn as Choke may aid in pattern; and this is the
conventional failing point for J-poles. As for using a 4:1, what for?
Isn't the J-pole designed for a match already? If not, go a more
conventional route.

>- I also note the J-Pole hairpin/matching section is never quite
>balanced as the load Z at the connected vs non connected ends skews it
>some. (From cebik) To my mind this has two thoughts, is it worth skewing
>the feed point (eg one side of the feedpoint 1/2" below the other) and

Skewing, as you use it, is somewhat ambiguous. Moving the tap will
move the match, not the balance. Further, it will probably increase
what you perceive to be a problem.

>does (static/lighting) grounding the supposed electrically neutral point
>affect the efficiency/pattern of the thing.

It is actually, electrically grounded. Being neutral is a condition
of wavelength and distance. The combination of those two find a point
that is insensitive to attachment (there are folded dipoles that mount
this way).

>- Wondering if feeding from one end results in ohmic losses reducing the
>radiation from the upper element.

Ohmic losses will remain regardless of where you excite an antenna.
That is, unless you remove the loss. You don't say how you accomplish
THAT by moving the feed.

>Thus skewing the pattern undesirably upwards.

A different skewing I see.

>I heard this use to be a big problem with early UHF coaxial
>collinear antennas. Mounting upside down was supposedly a good fix!

Yeh, sure.

>- I had thought for ages that skying radiation from ground effects is

Skying? More skewing? Ground "effects?" An air dam for the bumper
of your antenna?

>actually a function of the amount of radiation that goes at a downwards
>angle. (ie a perfect antenna is one that doesn't radiate below the
>"horizon" in free space)

Umm, perhaps.

>If one uses a 5/8 element for the antenna's
>mentioned above the normal high lobe one gets might contribute to this
>problem.

5/8ths antennas were never built for problems, how did they suddenly
arrive at this juncture?

>In other words is it better to (say) use 3x1/2 wave rather than
>2x5/8 wave elements in either an EDZ or JPole setup. (I'll be modeling
>this for my own interest but would appreciate feedback)

No. They are two distinctly different antennas. Note that 12/8ths
does not equal 10/8ths. Note even remotely.

>- This of course begs the question as to whether one should even be
>concerned about ground reflection on 2m with a 30ft mast!

Concerned? You sure have your priorities mixed. Maybe you should
dive right into modeling and resolve this through lifting a simpler
antenna through various elevations to find out what the consequences
are. They are many and varied.

I am aware that the traditional method of comparing mobile whips is by some form of field strength measurement near to the transmitter antenna. The measurement needs to be performed sufficiently far from the antena to be in the "radiation far field" zone for meaningful results... but is still potentially affected by the nearby environment (ground, structures etc), and is a measurement of performance at near zero elevation.

I did some thinking on a more meaningful end-to-end test, and described a technique at http://www.vk1od.net/lost/mobiletest/index.htm , which may be of interest.

As far as I can understand from its meagre online manual, it is an e-field probe (at low frequencies), and uncalibrated.

I have peformed some field strength measurements using an untuned small square loop, with balun and (50 ohm) crystal detector feeding a digital multimeter. Knowing the Antenna Factor of the loop from NEC models (http://www.vk1od.net/SmallUntunedSquareLoop/ssulNEC.htm) and having a measured the crystal detector DC output vs RF input, I was able to make measurments of absolute field strength which reconciled with other (albeit non-traceable) measurements and modelled expectations. I am working on a development of this kit that uses a LCD panel meter / diode detector / termination for a self contained portable field strength meter. Another variation being considered is using a log detector IC (DC - ~500MHz) for the termination / detector.

Anyway, it may be of interest.

As for calculating efficiency, won't you need to integrate the power flux density over the hemisphere... a much bigger task than making FS measurements on the ground at a hundred paces.

Einstien contribution was that he made the connection between matter and
energy. The fact that the speed of light appeared to be constant regardless
of the observers reference was already fairly well established before
Einstien began his work. He just proposed a possible explanation

If you are actually looking for EmComm antennas (as well as the test equipment, I would strongly urge you to look at the screwdriver. In addition to blowing the socks off the hamstick/Hustler, it has a flexibility that is amazing. For example, if you are looking at fixed and fixed-portable operation, the screwdriver can be used as BOTH a mobile system OR a FIXED antenna. Simply make a "half-dipole" arrangement with a random length of wire, a rope and the usual insulator. Remove the whip, and, using a 3/8" X 24 TPI bolt, attach one end of this one-pole(?) antenna to the top of the screwdriver and sling the other end (rope) into a nearby tree. You can then tinker with NVIS, high-angle slopers, height of the wire, or the mobile whip to get whatever configuration that works at the time PLUS quickly QSY to ALL frequencies of interest. Of course, the longer the wire, the better it works on the lower frequencies and you will lose the higher ones. But you can make more 'poles to put in your kit to account for this and/or place the whip in a variety of positions. LOTS of ways to play with this. The screwdriver is definitely the way to go!

Has anyone modeled what happens to the signal of a triband 3 element antenna that has one or more of the elements that has slipped on the boom say 10 or 20 deg ?

Also saw in an old magazine an antenna for 2 meters that had each element offset by about 5 or 10 deg around the boom to produce circular polarization. Will this actually work or is it wishful thinking ?

When it is all said and done, *I* would go with a single 102" whip cut for
10 Meters and mounted via ball mount on the left rear fender. This will
work well, it is simple, and you will not be able to measure any appreciable
benefit as to pattern or gain with any phasing arrangement. The thing about
"cophasing" is more hype from the CB world (gullible people buy MORE
antennas if they think some gadget will work better ;))! To each his own,
but I wouldn't go to all the trouble.

I've modeled similar things for sensitivity analysis of a design.
>From a theoretical standpoint, what happens is that the mutual coupling between the elements is reduced (to a first order, by cosine(angle)), which changes the amplitudes and phases of currents in the elements.

Net result.. not much change in forward gain (unless it's a very high gain design with a lot of superdirectivity), pretty big changes in F/B, if it was previously optimized for that. (that is, the nulls get shallower.. a 1% change in currents can make a 20 dB null into a 17 dB null)

As for making CP.. it might work, it might not. depends a lot on the design. A Lindenblad makes CP with two elements about 60 degrees apart. On CP in general.. it's easy to make elliptical pol.. tough to make perfectly circular. This is particularly true if you want CP in multiple directions (and it may not even be possible, depending on how many directions.. viz the "hairy ball theorem").

With all due respect, Jimmie, I am looking into creating a better
antenna system than the conventional dipole-on-the-back-of-the-CJ,
even if it was adequate for you. I like antenna theory.

After you thrash your way through the ARRL Antenna book (which
includes a CD with the entire searchable text.. very handy, as well as
some useful planning programs like HFTA)...

Another book that is quite useful are ON4UN's Low Band DXing... yes,
the focus is on 40m and down, but there's lots of good construction
info, as well as matching networks, etc.

And, finally, I think everyone who's seriously fooling with antennas
should get a copy of J. Kraus, "Antennas". This is a standard
textbook on the subject, and I find it much more accessible than, say,
Balanis, although the theoreticians tend to prefer Balanis, because of
the rigor.

Finally, if you need math stuff for antennas.. Sophocles Orfanidis at
Rutgers has an online electromagnetics and antennas textbook that I
find very handy (because it's online, and you can download the pdfs
and carry it with you on your laptop)... http://www.ece.rutgers.edu/
~orfanidi/ewa/ Orfanidis also has a bunch of very useful Matlab (or
Octave) routines as an appendix to the book.

I do to, but I also have learned from experience. I think co-phased mobiles has become just a CB trick to sell more antennas. I do undurstand it has a pratical side when truckers use them to overcome blind spots but this is nt needed on a small vehicle(more experience). Where else have you ever seen dual antennas except for CB. Let me be the last one who would ever discourage a person from learning by trying as I have tried some really wierd stuff before.

They also should point out that, although a radiator physically/electrically shorter than needed for first self-resonance can be "loaded" to resonance, this does not mean that loaded and self-resonant radiators perform equally well in an installed system. In some applications there can be as much as a 100:1 difference in their radiated powers, for a given power at the transmitter output connector.

Good point, Richard. An antenna's ability to "load"
is proportional to its electrical length. An antenna's
ability to radiate seems to be proportional to the
physical length of the antenna that is carrying the
highest current. In 75m shootouts, the mobile antennas
with the loading coil furtherest away from the feedpoint
(closest to top-loaded) generally won the shootout.

1131. Yagi antenna design question

Newsgroup: rec.radio.amateur.antenna
Date: 2007-02-04 14:39:49 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <45c5f035$0$36013$4fafbaef@reader4.news.tin.it>
Source record: 46143

I wonder whether anyone can formulate a convincing answer to the following question.

Let us assume you wish to design a 3-element Yagi antenna for good performances, but with NO REGARD AT ALL TO ITS IMPEDANCE (i.e. assume that you anyway intend to have a matchbox at the antenna terminals, so that the antenna impedance is of no concern at all for you).

At this point you run a good antenna design program, giving it no constrain in terms of antenna impedance. The program will give you the "optimal" solution in terms of element length and spacing, typically also showing the antenna impedance at the feedpoint, that we here assume to be e.g. 30 ohm.

At this point you change your mind and, instead of using a 30-to-50 ohm matchbox, you decide to match the antenna to the cable using the well known hairpin technique, by which the radiator length is reduced somewhat (to create some capacitive reactance in series with the antenna resistance) and an inductor is put in parallel to the antenna (to resonate the residual capacitance after resistance transformation).

Doing so the radiator length will result to be shorter that the length calculated by the computer program, and one could then presume that the actual antenna radiation characteristics (gain & front-to-back performance, radiation pattern) do not correspond to those calculated by the program any longer.

Even though the changes may be small, I would anyway be interested to understand whether, in principle, the hairpin technique results in a change of the antenna radiation characteristics.

If the change is confirmed, we would inevitably also come to the conclusion that the antenna radiation characteristics depend on the technique which is adopted to match the antenna to the cable (e.g. matchbox or hairpin). This would sound real odd!

Thanks and 73

Perhaps unexpectedly, the intrinsic pattern and directivity of a physically/electrically short, unloaded monopole radiator are not greatly different than those of a self-resonant 1/4-wave monopole. The big problem with an unloaded, short radiator is the reactance at its feedpoint, which means that very little current will flow into the short radiator from any practical r-f source. But for the current that DOES flow in it, its radiation performance will not be much different than that of a self-resonant 1/4-wave monopole, at that same current flow (as NEC will show).

Using a "loading" reactance to resonate the radiator allows maximum power transfer from the r-f source into the feedpoint. But the remaining issue is the low radiation resistance of the short radiator even when it is resonant, which is a small fraction of the other series resistances in the antenna system (ground and coil loss, mostly). As a result, much of the available transmitter power produces heat rather than EM radiation.

> Has anyone "fixed" this problem with their late model MFJ ???

I have an earlier "Differntial-T" model 986 that I bought in 1992. After a couple of years it would get very stiff in certain places. I disassembled it enough clean the grime out of the bearings and then used petroleum jelly as "grease" sparingly applied. It still works very freely and I haven't had to do it again.

I have to say that the finger dimple knob has not impressed me on the later tuners when I've played with them at hamfests as they just seem very stiff. Mine has the extra sub-spinner knob which works very well even after all these years. Hopefully this 986 won't give up for a while yet, but I only use it at 100 watts.

Theoretically yes, but not so much in practice.

Without losses, an "infinitesimally short" linear dipole has >91% of the peak directivity of a self-resonant 1/2-wave dipole (1.5 vs 1.64). And for a given applied power both of them would radiate the same total amount of power, just with marginally different pattern shapes.

The problem is that system losses in a real, "loaded" short antenna can be much higher than the radiation resistance, so a loaded short antenna may not radiate much of the available power -- in some applications not even 1% of it.

Hi Tony,

That is a good start for discussion, but you abandon this care-free
attitude almost immediately:

>...that we here assume to be e.g. 30 ohm.

Chances are it will be much less, possibly 5 Ohms. So, you see, you
have already introduced a constraint, and you continue adding more:

>At this point you change your mind and, instead of using a 30-to-50 ohm
>matchbox, you decide to match the antenna to the cable using the well known
>hairpin technique, ...

Which leads to another constraint:

>Doing so the radiator length will result to be shorter ...

As you are using a modeler from the beginning, you should also use
these constraints from the beginning.

Perhaps you are thinking of this as a two step process starting with
no constraints and then adding them. That works too and it requires
you to perform successive refinement. You can not escape this anyway.

>If the change is confirmed, we would inevitably also come to the conclusion that
>the antenna radiation characteristics depend on the technique which is adopted
>to match the antenna to the cable (e.g. matchbox or hairpin). This would sound
>real odd!

The change could be small. The question is how much change makes it a
"real odd" result?

From: "Fred Ferley"
Message-ID: <38ccs2hb61grv0585odlmg3duj0r03mspi@4ax.com>
Source record: 46151

Hi,
Hey, those "J" pole designs from off the `web you see are pretty
much Plug & Play for the most part. If you go through the steps
listed in the construction plans, everything's been already worked out
for you. . . These antennas are extremely solid for the most part,
and I've found that they work darn well at thirty feet up, grounded
and un-grounded too.

The only reason I could see for re-working this wheel, is if you
were going to mount it real close to a metal structure or of you were
going to try and parallel them for some strange reason, then you'd
need to do the required math. However, that would only be relative to
the distance between items, not the individual matching. .. Just a
simple attachment to the right location on the antenna, and you are up
and running.

Trying to tweak anymore out of one of these things nowadays with all
the bugs already worked out for you is like trying to squeeze out a
few more ounces of torque from your lawnmower: It may be possible
with great effort, time, and money. . . But why bother?

With my copper pipe "J" pole, I had a 1.1:1 match, and was hitting
repeaters 200 miles away on 50 watts. . . No calcs. Just lay it out,
solder it up and stick it up into the air! About three hours from
"Pipe" to "Antenna".

Maxrad makes a base loaded quarterwave that looks like their other land mobile offerings that covers the 10m band. I bought two with NMO style mounts and they worked very well for 10m several years ago. The reason I had two whips was one cut for the low end of the band and the other cut for the FM portion. When 10m was open I had no problem working everyone I heard.

The nice thing is that they are reasonably low profile--on the order of a 5/8 wave whip on 2m--and work very well with a typical NMO magnet mount on the roof of my S-10 pickup.

Have fun!

Tony,
by using hairpin matching, you take out portion of the highest current on the element and fold it into the hairpin where it is taken out of antenna "participation" for the price of match.

Better solution is to feed the element off center (K7GCO idea), find the 50 ohm point, insert the insulator and feed it with balun. This way you preserve the full size of the driven element and its coupling to parasites and higher antenna efficiency.

Better way is to use quad elements where the stacked elements, higher impedance and full size elements produce most gain per boom length (up to 5 elements)

Depends on how accurate a result you want.
I just use a signal generator and zero beat it against the received signal.
Use a counter to measure the sig gen freq. Accuracy all dependent on your
equipment.

But here is the accurate way to do it --- The ARRL sponsers a Frequency
Measuring Contest each year

See URL:
http://www.arrl.org/w1aw/fmt/index.html

Details and equipment
http://www.arrl.org/w1aw/fmt/2006/2006fmt.pdf

More detail at URL:

One other possibility: tho dont know if they still
supply samples, and the stuff is SPENDY! An
outfit , in Portland Ore. has couple of products
geared to power companies/ electricians. It is
Cool-Amp , and has a powder that will silver plate
copper (and other) metals. They also have a
SILVER bearing grease called Conducto-Lube. and
as stated, would use VERY,VERY SPAREINGLY, but,
would lube a roller inductor's bearings,
provideing great continuity . Don't think would
be something you want to use on the inductor
surface, tho.
(this stuff made for knife switch and breaker box
repair, of high resistance problems) . Also great
for UHF/ Microwave DYA components, to silver
plate them ! Try Cool-AMP.com Even if cost
$5.00 for sample,
would be worth it! Jim NN7K

Simple! Mount a 1/4 wavelength vertical on a mount that is well fastened to the bumper/frame with good ground straps or spot welded.

Forget about the whole CB thing of co-phasing.

Ten meter mobile is the easiest HF mobile installation you can ever do.

In that case I must be :-)

Can you elaborate why would I be kidding?

As far as I know:

If you use hair pin inserted in the middle of the element, you get the shorter physical length of the element - smaller high current carrying length.
Half wave resonant element has maximum current in the center, by folding portion of that element into a hair pin we take that portion "out of the picture". Just like a loading coil at the base of the vertical - current drop along the coil.

Hairpin is usually folded back on the boom, 90 deg. to radiator, with any current left, not participating in the plane of the elements.

Hairpin loading stubs were proven to be worse loading elements than good quality coils.

You would be better off by inserting coil at the feedpoint instead of (Beta match) hairpin, or use Delta match, or offset feeding at the 50 ohm pointas mentioned before.

We might be splitting hairs here, but I hate to lose even fraction of dB if there is a better way.

I know Beta match works, I used it in some antennas (don't like Gamma matches), even made a QSO with a ligthbulb as an antenna. It's all relative. Contesters like to chase every fraction of a dB lost, soon they can add up to some noticeable real dBs.

YMMV

Nelson, I would agree with Jerry as to the antenna choice. Cophasing
won't do much for ya, and halfwave is getting out of hand for 10 meters
mobile.

As a thought, in amateur mobile, where Ops are trying to pull out every
last bit of efficiency, the cophase antenna just isn't to be seen. The
biggest problem with them is that the logic is almost irresistible. Two
antennas just *seem* like they would be so much better than one.

That being said, experimentation is great fun, and you can get mobile
antenna parts at hamfests, or even make your own.

Actually, a 102 inch whip has a feedpoint resistance
closer to 50 ohms than does a 98 inch whip. A series
cap will get rid of the inductive reactance and then
one does have a fully function 102 inch 10m whip.

> finally, how do you measure the freq of a received signal? what equipment do
> you need?

There are many ways. It depends some on just what signal you are receiving. If there's a carrier, you can use different techniques than if there is not. From simple and not terribly accurate to pretty good...you can simply look at the dial (analog or digital) on your receiver. The old BC221 and LM military frequency meters were basically just reasonably stable VFOs with a built-in crystal calibrator and a calibration book, and you could use one of those to zero-beat with the signal and read off the frequency. You can use a frequency counter to measure the generator you've zero-beat with the signal, or alternatively, the local oscillator(s) in your receiver. For an SSB signal, you should be able to get within 10Hz or so if you tune the receiver for the most natural-sounding audio; closer, perhaps, if your ear is good. Then you have the frequency of the carrier that was removed from the SSB signal. For best accuracy, I like FFT techniques. I can connect an antenna directly to an FFT-based spectrum analyzer, and measure carriers to a tiny fraction of a Hertz in a relatively short time, better than a frequency counter if you understand the filter shape of the FFT "bins". But if you're receiving the signal via a path that is not absolutely stable, you are only determining the frequency of the received signal, not the transmitted one. During the ARRL frequency-measuring tests, I'm limited by propagation from Newington to the West Coast. But another advantage of FFT techniques is that you can see the spectral "spreading" that accompanies a varying path (or a carrier that's not stable), and estimate the error. If you measure during a time that the path is changing monotonically, there may well be a shift that makes it difficult to figure out just what the error might be; that happens typically twice a day, whenever the receiving point and transmitting point are not both in daylight or darkness. Of course, you need a way to calibrate your frequency reference for the best possible accuracy. A GPS-conditioned oven crystal standard is probably about the best you'll be able to do economically most places.

Cheers,
Tom

Hi Chris,

Based on my hardware 2m modeling, my and others conclusion is that going over 5 elements, quad array does not provide more gain per boomlength than Yagi.
This is why I tried to come up with design that would provide maximum gain per boom length, 50 ohm impedance and clean pattern - Quad/Yagi combination.
My conclusion then was that one quad element before and after driven (cell) element and rest should be Yagis.
Now I am playing with dual polarization designs, where quad elements are only "dumb" enough to not know which polarization they are at. By switching or phasing driven element one can take advantage of that property.
That, combined with new SDR and DSP radios is opening up whole new area.

> polarization. Will this actually work or is it wishful thinking ?

Ralph you are getting very close to reality.If all your elements are
close to individual
resonance then slippage upto 30 degrees will be to your advantage. At
the same
time your total gain will consist of the addition of all other
polarizations including circular

With respect to the 2 meter antenna, if I remember correctly the
successive angles must
be between around 20 to 30 degrees and none of the elements will
measure a half wave
length since they must all be resonant despite the coupling effects
which adds to
complications in manufacture.
Still if you feed one element at a time you can eventually get to
Eldorado, if not then
get in touch with your requirements and I will provide the dimensions
and if you have
any doubt you can use your own program to check its validity.
Have fun
Art

What is this 'whole new area do you see opening up' have with respect
to antennas and how is it connected to polarization ?
Myself, I anticipate some movement to more compact forms of arrays to
meet WIFI trends , erther way antenna interest is sure to increase in
the
next decade.

With two antennas and dual SDR receiver you can already swing the pattern
from the antennas in the software. Using dual polarization you can minimize
the efects of fading and take advantage of some noise canceling in DSP -
software. Even now you can see the signals before you can hear them.

Hey Yuri,
Will a Razor work better if it is looking out over an infinite salt marsh with
3000 miles of ocean on the horizon, or a sand-soil forested area? Just
curious. Assume 40 meters or maybe 80 meters and lots of height.

Anything works better over salt marsh or water. Vertical polarization takes more advantage of the "salty" effect.

I believe that your first problem is that you are considering the
hairpin (Beta) to be part of the radiator instead of considering the
actual case; it's part of the matching network.

> Half wave resonant element has maximum current in the center, by folding
> portion of that element into a hair pin we take that portion "out of the

op cit. I'm not "folding a portion of the element." If you subscribe
to the idea that part of the antenna can be "folded into" the feeder
and that by selecting the right feeder length you can "lengthen the
antenna" (as shown in a lot of old ARRL literature) then I have a new
limited space antenna for you. It's a one foot long radiator with a
variable length feeder (a la Cecil) that "makes up" the missing
antenna length.

>
> Hairpin is usually folded back on the boom, 90 deg. to radiator, with any

If I placed a discrete (lumped element) L-network at the feedpoint the
current in it would not be "participating" either.

>
> Hairpin loading stubs were proven to be worse loading elements than good

When, where, by whom, etc? Oh, BTW, did I mention "THE HAIRPIN IS NOT
A LOADING ELEMENT. It's the inductance in an LC L-network.

>
> You would be better off by inserting coil at the feedpoint instead of (Beta
> match) hairpin, or use Delta match, or offset feeding at the 50 ohm pointas

Why? The hairpin will handle all the power an amateur can supply, it
can (does in my case) form an integral balun and it DC grounds the
element.
>

> We might be splitting hairs here, but I hate to lose even fraction of dB if
> there is a better way.

No gain is lost. I can model my Yagi with and without the Beta,
resonating the antenna without it by lengthening the element and the
gain remains the same within 0.01 dB.

I've been a moonbouncer, I know all about fractions of a dB.

Do you have to shorten the (driven) element if you insert the hairpin in the
middle or not (to maintain the resonant frequency)? Telrex 40m Yagis did use
hairpins at the center of the element as a loading and shortening the
element length. To me that is the matching network too, but at the expenses
of shortening the element length - center loading, similar to base loading
the resonant quarter wave vertical.

You fold the portion of the element, it's called loading, at the base, in the middle or anywhere along the element length. The folded hairpin has inductance, just like a coil, and can be replaced with the coil of similar inductance. The loading element is not the limited space antenna, look at the currents at its ends and see the difference in curent distribution along it and how it participates in the overall radiator current distribution and corresponding area under the cosine curve representative of the efficiency. We are back to the loading coil "problem" and that's why we pointed out the efect and its impact on the antenna performance.

>

Here we go again? We are talking about standing wave circuit - antenna radiator or element. So inductance is not a loading element? As far as I know inductance (coil, hairpin) or capacitance (top hat, L, T loading) are used as a loading elements to shorten the physical length of the antenna element, while maintaining electrical length.
There was an article by W6?? in CQ and other examples when they replaced hairpin loading on Yagi elements with coils and got significant improvement in the performance of KLM 3 el 80 Yagi, better gain, much better pattern due to less interference of the folded back hairpin with the element. Measurements and modeling before and after showed that.

pointas
>> mentioned before.
>
> Why? The hairpin will handle all the power an amateur can supply, it

>about 320 feet... any particular reason I shouldn' t do that?

I used to have a "dipole" which was about 150 feet on one side and
closer to 200 feet on the other, fed with true ladder line (little
plastic insulators spaced every 6 inches, not the plastic-covered
stuff) up maybe 35 feet. Worked like gangbusters. Locals often
explained that I "got out" so well because my signal was halfway
there before it had to leave the wire. VSWR was often greater
than 10:1, but I didn't care.

Why didn't I think of that? The SWR on the ladder line on 40m
would only be 47,000,000:1 and the feedpoint impedance would
be 10 micro-ohms at system resonance.

Your "one post thread" statement got me to wondering. If the moderator doesn't like any of the answers to a question, do they "moderate" the answers? (I'd use censor, but I fear I may have been abusive of the more delicate readers here) Is the moderator duty bound to m-moderate incorrect answers?

Is there any legal responsibility in all this? Which is to say would the cen... dammit! Moderator have any responsibility to block our posts about charging up capacitors in school, and shocking people with them? Are they leaving themselves open to litigation?

Would posts about Isotron Antennas be allowed??

Hi Fred

Tnxs for your comments

The issue however isn't to do with the (available) design of the JPole itself, but whether it is better to use an EDZ instead of it. ie What are the disadvantages/advantages. The points I made were the ones I was "using" in the decision making process. You'll also note that I am looking at the "Super 5/8-5/8 JPole" of which there are far fewer designs available.

Cheers Bob VK2YQA

The total distance between the transmitting and receiving antenna of a microwave link at 10GHz, is 30 Km. the height of the Tx antenna is above ground level is 20 m. the maximum acceptable total path loss is 169 dB. Furthermore there is hill located 10 km away from the transmitter antenna with a height of 80m.

calculate the height of the receiver antenna for the path loss to be just equal to the maximum acceptable value?

> calculate the height of the receiver antenna for the path loss to be
> just equal to the maximum acceptable value?

1. Antenna essentially operates in free space with no near field ground losses because the wavelength is extremely small (3.3cm) compared to 20m antenna height at the transmitter.

2. The effect of the 80m hill 10Km away is negligible. The arc tan is only .008 degrees, thus the transmitter hardly "sees" it.

3. The path loss seen by an atenna at 0 feet is then 131.8 dB (Path Loss = 20log(4*pi*d/lambda)), which is much less than the desired 169dB maximum.

Answer: 0 Feet.

Oops, that's a path loss of 141.16dB. Same answer, however.

Actually, Stefan, the transmitter cannot see through it at all.

>Answer: 0 Feet.

Our Lincolnshire student needs to think back to simple trigonometry to
answer this. The path loss, once the height of the hill is made
irrelevant, is sufficient as Stefan points out.

The only way I could figure the hill in is if one is trying to Knife-edge
over the hill. Otherwise the hill is totally irrelevant to the problem.

I will make my (usual) pitch for the j-pole antenna.

Take a look at http://www.hamuniverse.com/jpole.html and see what can be done at UHF/VHF with a few pieces of pipe, some solder and a torch. The j-pole is a good match after a little fiddling, It's durable, requires no ground plane and can be mounted almost anywhere. I have made about two dozen of them for myself, for RACES and for friends in the local club. My first one (early 90's) is on the roof of my house and I used it on 2m earlier this evening, as I do most evenings.

Search google.com for jpole antenna and see about 40,000 other links.

The "quad antenna" and its cousin the "quagi," a quad/yagi hybrid, are also possible, but I've never built any of them, myself. The venerable whip-over-downward-radials is easy but can be tedious to tune for a good match. (I built one of them onto a construction hardhat as an novelty; got a good match, too.)

I'm next door to you in Chula Vista, by the way.

Whats the height of the receive antenna?

Is the hill directly in the line of sight of the receive antenna?

Exactly . And taking into account the 15 degree bend of the radio horizon
(even at 10 GHz) vs the arctan of .008 degrees for the the hill, reduced
somewhat by the 20 foot transmitter tower to .006 degrees, the hill itself
is invisible at a 30km far field. The bend of the propagating waves which
extends the radio horizon clearly mitigates any possible effects of the 80m
hill.

Hi Stefan,

You seem to be simultaneously agreeing and disagreeing. The hill is
either in the way, or it is not. It is in the way. To count on an
intermediary, such as suggested by Jimmie, knife-edge propagation or
bend of the waves, is probably not in our student's syllabus. Besides,
I have seen neither you nor Jimmie offer the attenuation presented by
such refractions (and the attenuation is not marginal). Without
quantifiables, the path budget cannot be calculated.

The problem, as stated, has a clear answer in looking over the hill by
raising one antenna, the question informs us that is the answer and
that is simply resolved with trig (albeit, including the radius of
earth and accounting for its curvature).

>
> Answer: 0 Feet.

Definitely NOT 0 feet.

Even without the hill in the way the curvature of the earth means that the
radio horizon is at about 20km with the tx on a 20m mast. 0.6 Fresnel
clearance occurs at about 6km. and the path loss exceeds 180dB.!!
The Rx mast needs to be at about 25m to obtain a 0.6 fresnel zone clearance,
WITHOUT a hill.This would give about 150dB path loss.

Adding the 80m hill at 10km gives a single knife edge diffraction, that
increases the path loss enormously to about 200dB!!

This path loss does not change significantly until the Rx antenna height
gets so large that near line of sight is achieved. That is over 100m!! To
obtain the 169dB required figure the mast height would have to be about
250m!!!!!!!

My mother lives in a area where the cell-phone signal is very weak. Typically I can get only one mark on the phone field strength meter. That forces me to go outside the house in order to have a reasonable chance of completing a call (of course only if the weather permits). I have only basic understanding of antennas, so I am asking this forum if the following idea is feasible.

I am planning to build (or buy) a 850 MHz Yagi antenna (14 dB gain) to be installed on the outside and pointing towards the signal strongest direction. The boosted signal would be transmitted through a balun and a low loss 75 ohm coax cable to the inside of the house terminating to a 1/4 wavelength 75 ohm antenna stub. Is this feasible? Could I get perhaps a 10bB signal boost inside the house by means of this arrangement?

TIA
Gene

The height above mean sea level of the tx and rx sites, and the terrain profile for the path would be necessary to answer this ~ accurately. But for a smooth earth model, the graphic at the link below will give some insight.

It shows that a height of around 270 meters would be needed for the receive antenna, using a K-factor of 1.33 and 0.6 fresnel clearance for an 80 m hill 10 km downrange. The path loss then would be about 142 dB.

This will be the last word I have on this topic.

I have placed two files here:

www.k6mhe.com/n7ws/N7WS_Yagi_Resonant.EZ

and here:

www.k6mhe.com/n7ws/N7WS_Yagi_Shortened.EZ

The files are models of my 20-meter three-element Yagi that are as nearly representative of the physical antenna and its location as I can make them. The only difference between them is the half-length of the DE. The actual antenna uses the shortened version with a stub (Beta) matching/balun arrangement.

Two photos of the details of this are here:

www.k6mhe.com/n7ws/YagiFeed-1a.jpg

and here:

www.k6mhe.com/n7ws/YagiFeed-2a.jpg

The photos were taken with the antenna mounted on the tower and the tower folded over in case you're wondering about the orientation.

For the purposes of the discussion I have removed the stub matching system from the model.

The following transformation and matching exercise can be performed using a Smith Chart, your favorite computer program or with pencil on the back of an envelope. I happen to prefer, and highly recommend, AC6LA's XLZIZL.xls Excel workbook for this stuff.

First let's analyze the full-length, resonant DE version. After running the analysis we (should) have a feedpoint Z of 26.76 +j0 and a gain at the selected elevation of 12.91 dBi. The SWR is 1.87:1.

Instead of the integral stub, which Yuri believes is part of the antenna that is "folded back" along the boom, I will move the matching system away from this location using an ideal ½ wavelength (34.7 foot) transmission line with an ideal current balun at the antenna end. I don't believe anyone would argue that the feedpoint impedance is not replicated exactly at the input end of this line.

At the input end of the lossless line, the Z is of course, 26.76 +j0. Because, as will be shown, the stub matching system is nothing more than an L-network; I will use the same at the input of the half-

wavelength line.

I begin by inserting a series capacitor, C = 448 pF and Q = 1000. At the input side of this capacitor the Z is now: 26.785 -j25.062. If using XLZIZL, the loss in this capacitor is shown as 0.004 dB, because Q is not infinite.

Continuing, I place a shunt inductor, L = 0.6, Q = 200 across the input of the series capacitor. The resulting input Z = 50.00 +j0.2. The total network loss is 0.02 dB. This is the baseline.

Returning to the shortened driven element version, after analysis, we find that the input Z = 24.55 -j25.2 and the gain is unchanged at 12.91 dBi. At the input end of our magical ½ wavelength line, the Z remains 24.55 -j25.2.

Once again using the L-network system, I find that the series capacitor is unnecessary and I can proceed by adding a shunt inductance. Rather than using Yuri's "preferred" discrete inductor, let's use a "lossy" stub. Instead of using the large diameter, parallel tube stub of the actual antenna, I'll use a standard transmission line for the stub. XLZIZL has a number if transmission lines and their parameters "built in," including the Wireman ladder lines. The parameters for these are those I derived in my ladder line paper.

http://www.k6mhe.com/n7ws/Ladder_Line.pdf

Selecting Wireman 553, shorting one end and placing the other in parallel with the input to the lossless line and doing a little manipulation and I find that a 14.85" length makes the Z = 50.12 +j0.18. The network loss remains 0.02 dB. So much for this less than ideal stub vs. Yuri's preferred discrete inductor.

There you have it. The stub matching method is equal to a discrete L-network in efficiency, it does not detract from the antenna efficiency one bit, it can incorporate the balun function without additional components, it grounds the feedpoint, with a little sealant on the cable, it is weatherproof and unlike Gammas and Tee-matches, it will handle full power without being prone to capacitor breakdown. It is not part of the radiator; it is part of the matching network. Period.

1199. J-Pole vs Slim Jim?

At 10 Ghz the "hill" is a factor if the receive antenna is at the same
elevation or below.
If its higher it really is a non factor, if this remains true I would be
more concerned with shifts in temperature and if the signal travels over
a body of water.

Hi Wes,

A very interesting design and discussion. Thank you for posting it.

I could be wrong but I think Yuri's main point was that if [fill in the blank] loading unit radiates at right angles to the beam pattern (or out of phase with it) it detracts from the gain of the antenna. I think that's probably a reasonable claim.

Regarding passive repeater,

Only when you have a very strong signal outside (that means your house must be a very good shield), your suggested arrangement will work. The problem is in the path between your handheld and the quarter wave antenna inside your house.

Just 3 ft away from your quarter wave antenna the propagation loss is about 30 dB (at 850 MHz). Assuming about 3 dB cable loss, the overall loss (with respect to the handheld outside) will be about 20 dB. So this arrangement may give improvement only, within one meter of the quarter wave antanna in case of a building loss of more then 26 dB.

Probably you need a repeater system or connect your handset to the cable directly (via RF coupling or other means).

Best Regards,

Wim

What I did was to buy a collinear antenna made for cell phones from Radio Shack. On my cell phone there is a jack for an external antenna. My dad has the same problem. What we do is plug in the new antenna which has a mag mount base and set it on top of the refrigerator to produce an infinite ground plane. Works like a charm.

You might think about this solution.

Oy! I'm trying to imagine that, Cecil! Your long discussions with some people when y'all are disagreeing with some small point comes to mind. Seems like a moderator could do Editor's notes on your (or anyone else's posts that would automatically "seem" to declare your ideas as wrong.

Yeppers! That's the ticket! There's No Need to re-invent the
wheel, besides, it'd take you longer, cost more, and more than likely
NOT get any better gain. Besides, it'd probably look like some sort
of an experimental home-brew nightmare, huh?

You can buy one of these nice, compact yagi's on eBay, or just do a
simple Google `Net scan to find all the different companies who offer
such monsters. I've even seen some neat little jobs all made on a
tight little printed circuit board! But be aware the price variation
is WIDE when it comes to things like this, and so are the assorys.
Don't get any more than what you really need, and keep in mind that
once it's in place, the phone, well it's rather a "Stationary" set-up
if you want to use it from then on. In short, you have to keep it
attached to that darn antenna for it to do you any good, right? In
light of that, maybe a standard cordless phone may be the better way
to do things instead. . . ?

Well, there's my two-bits on this subject. It all depends on how
much mobility you need, and how many loose $$ you have to spend on it.

Don't ever sell the good ol' Di-Pole short! Besides being CHEAP,
it's easy to set up and take down, and not too annoying to the
neighbors ether.

If you got one set up, you can sling a wire under it and turn it
into a "Cloud Warmer", and that has a whole lot of interesting
possibility right there too.

Who is right, you or Jeff? You are more than 100% off from each other.

In truth, i could receive that signal holding a hand held 10GHz receiver while sitting on the ground. The 80m hill is nothing from an observer 10KM away...only .006 degree from the top of the transmitter tower. It is part of the horizon. I love it when you guys talk like you are sol knowledgeable yet lack the common sense to conceptualize the problem as it really exists.

Hi Stephan

Your posts seem to inply that the receive antenna will "see" the 20 meter high transmitting antenna when the receiver antenna is in the shadow of the 80 meter hill. It seems that the receiver needs to be out of the shadow of the hill unless you are able to estimate refraction from the hill.

But, your aparent confidance in the statement "0 feet" makes me wonder if I have this problem wrongly analyzed. I have so much confidance in Richard Fry's data that I had accepted his estimation of 270 meters to be as close as you can estimate.

Do I misunderstand your post about what minimum height is needed?

Jerry

On the SteppIR webpage, one of the photos is a SteppIR dipole mounted flush with the roof to provide stealth operations. I wonder whether this arrangement is worth it?

Is this too high tech / high cost for low return on investment?

Thanks in advance

Hi Stephan

Tell me where I have misunderstood the problem. I assumed the
transmitting antenna was Lower than the top of the hill. But, you seem to

imply that the transmitter can be seen even when the hill is blocking the "view" to it.

I have actually never measured a shadow longer that a few feet, but I assumed they continued to exist to infinity when an object blocks them from view.

Jerry

Well you see Jerry, the reason you only see it for a few feet is because the attenuation of the light varies inversely with the distance from the object that blocks the light. I think you have done a good job in making my point. Thanks,

Why would anybody go to all that expense of getting certain
desirables
from his antenna and then throw them all away by placing thr antenna
so close to the house wiring and structure. He might just as well load
his gutters to obtain stealth operation. I imagine that would be a lot
less money spent and he loses nothing when he moves house!

If you have room for a double Zepp then the best bet is the Moxon
dipole
with a resonator. It will supply the same gain as a zepp and has the
advantage
of operation over an octave by varying the value of the capacitor from
which
the resonatator is made of. This also removes the added coax stub
procedure.
required of a zepp.

Might I recommend a program misleadlingly called Radio Mobile. This piece of software will all let you check many real world situations. This program is not real easy to use, it's a lot worse than Windows or Office (ok, not worse than Office), but it is worth learning unlike the previous 2 mentioned.

The site you need for the software is

http://www.cplus.org/rmw/english1.html

and then you need to download a large amount of terrain data, which is freely available from NASA. It looks like the way this is handled has changed since I did it last, so I can't comment on how it is done now.

Hi tom,

I was involved in Beta testing this. The current version allows
dynamic map loading over the Internet, and overlays of Mapquest, Tiger
or many other mapping programs available. I've been using it heavily
for the last few months and its world of variables allows for finely
grained analysis. However, it also allows for massive headaches if
all you are looking for is a simple solution. In short, no
quantifiables are going to follow from your recommendation - unless I
do it. This lil Red Hen isn't interested in cooking that bread.

So you are saying that you can achieve 30km at 10GHz to a hand held receiver at ground level with a 300 foot hill in the way!!! I am sure that you could not do this with any sensible power even at 2m let alone 10GHz.

Perhaps it is your concept of what is going on that is wrong. Have you heard of Fresnel Zones??
When obstructions come within the first Fresnel zone significant attenuation occurs.

With the situation that you are describing the path is totally obstructed, with the path only possible due to diffraction from the hill top. The hill top impinges to at least the top of the 5th Fresnel Zone, hence the attenuation is very high.

As the height of the Rx antenna increases the attenuation is still very high until the hill top only start to intersect with of the first zone (antenna height~150m). It then drops quite rapidly until there is true line of sight and bottoms out when the hill top is clear of the second zone.

You make a great deal of the hill only being 0.006 degree at the horizon. If you plot it accurately and with reference to the Fresnel zones, it does make a big difference. With the Rx antenna at ground level the top of the Fresnel zones are never below the horizon, which is completely different to the situation when the hill is there (-5th Zone obstructed).

Also, without the hill you only have to raise the Rx antenna to about 15m to achieve line of sight compared to 200m with the hill there!!!!!! Quite a big difference I think you will agree, and one that your 'conceptualisation doesn't seem to allow for!!

There are lots of programs out here for calculating path loss for LOS situations but figuring in the path via knife edge defraction is something I have always tried to avoid.. In real life there are too many variables that effect this and you could have a signal that would tend to fade. Over the years I have forgotten or lost interest in figuring the impractical.

While visiting a mountain town in Arizona, a wonderful place with a terrible legal attitude toward antennas of any sort, I passed a house in an upscale area. All the houses were 2 or 2.5 stories. On the roof of one facing away from the road, I noticed a StepIR dipole installed much as the one is shown on their web site, though closer to the ridge. The picture shows a ridge vent, which if aluminum would require the indicated separation. I noticed a few of their verticals in use as well in the area, most "clearly" disguised as flag poles.

I had a chance to talk with the OM, and he said that while they certainly worked, verticals, inverted Ls, etc, were not easy to install in that environment due to the very poor soil and limited yard space to implement a good rf ground system. The result was relatively poor coverage, and RF in places you didn't want it. By contrast, a resonant dipole has far less extreme issues. He mentioned knowing of one ham who actually installed the dipole inside the attic, along the ridge line. While the lengths required a bit of tweaking, easy with the controller, he seemed very satisfied with the results. It seems a bit brute force, but sometimes the most effective labor saving device is the proper application of money.

N1GPK, the ham whose picture appears on the StepIR site, has a few comments in the testimonial section. I did not find his e-mail on QRZ.COM, but no doubt you can contact him from the other info.

All parts of any given galaxy are not moving toward or away from us at the same speed, unless the galaxy is perfectly perpendicular to us.

Is your red-shift issue about the red shift itself, or about the magnitude of the shift? And if "variable seconds" is the culprit, how are blue shifted stars accommodated in your model?

True, but consider that the red shift frequencies
are discontinuous, i.e. quantized.

Of course there is gravitational redshift too, but I don't think that is what you are referring to.

I think you are trying to say that time is variable (forgive if I err) This means that the speed of light is also variable if only by relation to that variable time element

Doppler effect is readily observable at audio and RF wavelengths. It is widely accepted that the effect continues at light wavelengths.

Any effects that alter Doppler at light wavelengths should also be noticeable at to wavelengths. I have not heard of any such, have you?

This then says that we are not in the "fastest time" zone, because there are celestial bodies that are blue shifting toward us, or perhaps not,they are just in a different "time zone"? ;^)

BTW, I erred in my perpendicular statement above. I forgot about transverse Doppler shift that we would indeed have in a galaxy at right angles.

The question is: Are all frequency shifts in the
universe caused by Doppler effects? I say no.
I say some frequency shifts are relativity effects.

The doppler shift of EM frequency is a relativistic effect, so you got
that sorta right.

There is an interesting (hypothetical) effect - and maybe this is what Cecil is talking about. Two systems; A and B, we're A. System B is moving away from us at relativistic velocity. Sodium yellow light from system B's street lights looks red from where we're standing in system A. Lets say we can also measure the atomic transition frequency of the sodium atoms in system B's street lights and discover that it resonates at a lower frequency compared to our reference frame. [Note that if the velocity between the two systems is indeed relativistic, then visible light will be shifted down into the infrared. Also note that if we could observe the diaphram of a car horn as it approached us, we would see that its frequncy of oscillation visually would be higher than its doppler shifted audible frequency.] If we assume that sodium behaves the same way everywhere in the universe (which we usually do) and it transitions at universally the same frequency everywhere, measured with respect to its own reference frame, then there must be a difference in the length of the unit time between the two reference frames in order to explain the apparent observed frequency difference. We usually assume the Doppler effect is linear with velocity, but temporal effects are assumed to increase very non-linearly as the speed of light is approached. So at modest velocities the apparent shift would be all doppler, but at relativistic velocities the temporal aspect would become more significant. I believe this is one explanation for the apparent 'acceleration' effect, where you look far enough out and things appear to be accelerating away from us, not just moving away.

Well... I've been struggling with getting HF antennas up in my CCNR challenged neighborhood. Given that one of the board members of the HOA can see my back yard directly and there are zero mature trees around here, I've had a lot of difficulty putting up any kind of antenna (without getting a letter from the HOA.) My current set up uses a coax trap dipole folded up in my attic, and it is horridly noisy on receive and nobody can hear me. (Being a single story house with all the electric in the attic pretty much tears it for me.)

I can see where such a set up with a stepper IR dipole might be about all you can do in some situations. It gives you good resonance on multiple bands and doesn't have much of a need for a ground. It may not be very efficient and it may be expensive but it seems like a valid option to me.

It won't be as good as it *could* be if you could mount it on a tower at the right height, but it might be all you can do in his situation. It also seems that it would be better than loading up the gutters on 75 Meters...

Correction: The car horn diaphram would of course be oscillating at a
frequency lower than the audible frequency when the car is approaching.

The "expanding" space between two galaxies could be
a relativity effect and the shorter second due to
relativity effects naturally results in a lower
measured frequency.

The doppler red shift is thought to be because
galaxies are receding from each other. If a
rope stretched between those galaxies doesn't
break with time, what would that imply about
the recession?

What if we and everything around us are still traveling
near the speed of light compared to the center of the
Big Bang? What if our velocity compared to the center
of the Big Bang is actually decreasing. Decreasing
velocity implies decreasing mass, increasing standard
unit lengths, and decreasing standard units of time
all of which might fool our measurements of today.

The Big Bang may have happened 12.5 billion years ago
based on the length of our present seconds, but
measured using the center of the Big Bang as the time
frame reference, how long since the Big Bang?

How about this: If the length of the unit time changed by a factor of two then the age of the universe, using the new metric, would differ from the old by a factor of two. Same amount of time, but a different number of units of time.

I'm sorry. I was unaware that the StepperIR had upgraded its multiband
antenna to include 75 metres
So all is still not known about antennas !

> solve this problem without making my antenna enormous.

If you build an amplifier at the initial recerving antenna which is
preferably
outside the house the signal within the coax leading to and within
the house
will be strong enought to overcome the losses entailed by using a
long
connecting coax. Placing the amplifier at the antenna prevents noise
from
overpowering the incomming signal The amplifier need only to be a
simple
transister driven by a battery. Remember that the signal to noise
ratio will
never be better than the signal recieved by your antenna before
amplification
which should provide the impetus to build the best antenna you can
build
and situated in the most desirable place for receiving..
Good luck

I think he means the AM broadcast band.. Or I assume anyway.
The loss with most any length of coax at that MW freq should be
dinky indeed.
I built one of those when I was about in 7th grade. Mine had like
a small tight wound loop for an antenna if I remember right. But I
might
have even tried hooking it to to my then SWL antenna which was a 50
ft random wire. I don't know how critical the transister? is as far as
match. If it's not picky, you could probably just string out a short
wire. There are probably FCC antenna standards as far as such a
device,
but I'm too lazy to look them up.. I don't think the FCC wants them
radiating too far. As far as receiving at MW, Any commercial radio
should be good enough with whatever antenna came with it.
Well, unless it's a really lousy radio.. :(If you can hear noise
in between stations in the daytime, it's good enough and can't really
be
improved too much as far as s/n ratio.

Hmmm... My bad, they do 20 Meters max according to the website (40 on their vertical model) ...I was thinking about the screwdriver antennas (High Sierra I think), not the StepperIR when writing my reply.

But still, it's hard to judge another man's antenna selections by their looks every time and be right. (although mine pretty much perform like they look.)

Anybody tried the MFJ rotatable dipoles? I might be able to hide one of those behind the house... :)

You sure about that? I don't think you can add gain specs
from say vertical + horizontal, and claim an addition of total gain.
You have so much vertical, so much horizontal, and so much if
circular if fed to provide that, and each much be considered
separately.
I don't think you can add them all together. Course, I'll eagerly
await if any
comments to the contrary..

Because of the effects of gravity and velocity upon
time, the first "second" was probably many magnitudes
longer than our reference second of today. And not
only does the length of a time unit change over time,
it also changes with position.

> What is a "reciever"?

ok. let me be more clear. my transmitter is a simple am-radio
transmitter. it is essentially an aduio transformer connected to a
1mhz crystal oscillator. i have, connected to my oscillator's antenna
lead, a simple telescoping radio antenna, and so my "transmitter"<----
[the am-radio transmitter] has to be just a few inches from my
"reciever" <----[the am-radio] for the "reciever" to pick up my
signal.

My question is: will this antenna, the loop stick antenna mentioned
above, boost the signal coming from my "transmitter" or will it just
allow my reciever to pick up the signal easier? or in other words how
will this antenna help me?

sorry if i wasn't clear enough before. i just thought you would
understand what i was talking about.

No I am not saring that! What I am saying is that an anterna can
radiate
in many ways at the same time. One or all of them can combine or
cancel
to provide a max radiation field. Why I mentioned that was if a
radiator was
horizontal which hams would normally favour would favour horizontal
polarization and other polarizations would suffer.
If the array did not favour a particular polarization by being placed
at an
angle to the surface of the earth you would hear signals at different

distances
because of various polarization signals one can receive. In other
words your
antenna covers a larger land area than say a horizontal antenna
alone.
This could well be why a Yagi appears not to hear as well as a quad
which hears a variety of signals from different distances but of
course
many would argue the validity of that statement just for aurguments
sake
alone.!
The Gaussian clustered arrays that I talk about are radiating arrays
of arbitary
positions and angles relative to one another such that they are
suitable for use
at any polarization required for advantage. Also because all elrments
are resonant
interchange of driven elements can be attained to porvide alternate
polarizations
a challenge that I understand Yuri is presently pursuing for various
reasons tho
I understand it is mainly to combat fading of signals, but he can
explain for himself..

Have you tried other carriers? At my house a Sprint only works
outside in the back yard while T-mobile and Cingular have no issues
inside. It could be that your carrier just has lousy coverage because
your house is to far away from their cell tower (or the antenna on the
tower is not pointed directly at you).

Another option is to complain to your carrier about signal strength
and hope they get around to changing it sometime soon (not likely by
the way.)

Third, is try another phone on your carrier of choice. I've seen
different phones have vastly different abilities under the exact same
circumstances even on the same carrier.

No one can tell how anything can help if you don't tell us what help
you need.

Being able to receive inches away speaks to an accomplishment, not a
problem. If you want to receive miles away, then the comparison
between what is accomplished and what is desired reveals the problem.

>sorry if i wasn't clear enough before. i just thought you would
>understand what i was talking about.

You never really "talked about" anything when the sum total of your
correspondence barely exceeds a half dozen lines up to this posting.

Now, we can all presume an intent, and that intent goes counter to
what is allowed by law, and that is long distance communication on
commercial frequencies by an unlicensed station. The law is
exceptionally clear as to how much power is allowed, into how large a
radiator, for unlicensed stations (such as yours). The long and short
of it is that without exceptionally good reception gear, that distance
is rarely more than across the room, or within a block.

Clearly, even these distances vastly exceed your current
accomplishment of a few inches because you could invest little more
effort into doing it with a modulated LED across the room. TV remotes
do this a billion times an hour world-wide.

Even with the allowed sized radiator, it is pathetically inefficient
(which is the intent of the law). The name of the game is called
matching, and a XTAL oscillator is a poor power source.

However, all of this is strictly window dressing unless the whole
scope of your Science Fair project is limited to building a working
transmitter. If so, you need to formulate better questions. If not,
you are spending too much time when you could build a Ramsey Kit in an
afternoon and get on with the grist of the project.

Version 4.1 improved on the basis of 4.0. Added show/hide track in addition to track removal. Also, the color in which the mobile station names are displayed can be customized. And you can set up a tactical call sign, and choose to beacon it instead of youe regular call sign. In filter settings, you can choose to accept stations in the track list without manually adding them. This version has improved legacy TNC support as well.

Thanks, Michael KF6ZDM

Polarity diversity is nothing new Art, the way you are trying to achive it, if that is what your guassian cluster is all about is the wrong way to go about it. First time you have even come close to describing what you are doing.

Outside antennas connected to your phone work very well. I used to have a
"bag phone " that we used in a cabin in the mountains. Total unusable in the
house, barely usable outside. Like you are next to the tower with a small
yagi atatched. Problem is most cell phones dont have an antenna conection
these days. Look for one that does.

>> down, or is it just there for decoration?

Thanks, Bob.
I did have a look around, but I missed that particular paper in W4RNL's
website (which is certainly a mine of information).

The gist of it is that there is negligible difference between the three
versions of this antenna.

One point which I did notice is that the feed point is lowest down for
the single-radiator J-Pole (Fig 2), higher for the 'Loose Wire' version
(Fig 4), and highest for the folded-over Slim Jim version (Fig 6).
Presumably, this is because the top part is effectively fatter for the
Loose Wire, and fatter still for the Slim Jim. This will lower the
impedance at the bottom of the top halfwave part, and you will need to
tap the feeder further up the quarterwave stub in order to find the 50
ohm point. There is maybe some confirmation of this in the SWR plots
(Fig 11), where the bandwidth for the Slim Jim version is somewhat
greater than the other two.

I'm guessing that you would only make a Loose Wire version if you were
making the antenna out of twin feeder.

Cheers,
Ian.

Here I become confused. It sounds as if you are saying that the
oscillation frequency of the "object" would be higher than the
frequency than the Doppler shifted frequency on approach. That sounds
like the reverse of the Doppler effect.

> measured frequency.

Could be. My questions alway revolve around just what - or why - the effect is. The great thing about Doppler is that it works on so many scales. We should be able to perform experiments that will go a long way toward determining if such an effect exists.

What I see however is that there are no great anomalies with the present model. That doesn't make it right, but it does mean it pretty much fits.

Relativity also works at speeds lower and more local than across the universe, Astronauts and their craft who orbit the earth are "younger" than they would have been if they stayed on Earth. We use accelerators that act consistently with relativity. We probably should see some of what you are thinking of.

1261. Antenna Pattern Distortion due to 2 antenna placed in near vicinity

Newsgroup: rec.radio.amateur.antenna
Date: 2007-02-09 16:46:02 UTC
From: Rohit <rksindhu@gmail.com>
Message-ID: <1171039562.001011.113640@l53g2000cwa.googlegroups.com>
Source record: 46075

Hi all,
I have placed 2 similar antennas (3 dB beamwidth = 90deg,
Polarization= LHC) on a PEC box with a small spacing between the 2.
Both antenna's are tilted and the first one is at 45deg and other at
135 deg from the horizontal so that both can cover 180 deg.

With this setup, in the simulation result i am observing heavy
distortion (about 10dB ripple or more) at 90 deg. What is the reason
for this heavy distortion. Is there any way i can remove the
distortion in the pattern without changing the antenna's position??

Thanks in advance,
Rohit

I could care less about books, although I do have quite a few.
I'm more convinced when I actually see something work.
If you are convinced this theory of yours has merit, why
can't you build one of the things and test it?
All this gaussian jibber jabber doesn't mean squat if you can't
build , test, and demonstrate one in the real world.
I read books, but I also usually test things in the real world to
verify the info is correct. Trust me, not much of what is in books
is wrong. Some is, but it's fairly rare overall.
If I were to come up with some new design, I would have built,
tested, and compared, before I even made any announcement
about the theory.
I get the impression that you cook up all these ideas, but
rarely actually test them in the real world.
That's no way to live, if you don't want the negative flak.
MK

Hi Rohit

I consider your antenna to be one antenna with two driven elements.
Wherever the individual patterns from the elements overlap, they will add or
subtract depending on their relative phase.
Can you consider switching to alternately choose one element or the other?
Can you change the pattern shape so the patterns dont overlap? What are
your choices?

Jerry

> with an am-radio across the room.

Hold on guys! T, this is a rarified group here, and sometimes it shows.

Okay, so you have a transmitter that is presumably transmitting somewhere.

You want to be able to receive the signals on an AM radio at some distance. Let's collect a little data, and I maybe I can help.

If you are using a typical AM radio to pick up the signals, you don't need to do anything with it. It's already got an antenna.

Now on to your transmitter.

If the transmitter is working, you should be able to pick up a pretty strong signal when the receiver is sitting next to it. Even if you just have a short piece of wire on the transmitter.

If you don't, it is possible that the transmitter is not working. It is also possible that if you have only a weak signal, you might be transmitting on a "harmonic" frequency. This is pretty much double or half, but it means that you are getting a much less powerful signal to the radio.

Assuming that your transmitter can be tuned, set the radio at some frequency, preferably on the lower part of the band and away from local stations.

Now, with the radio sitting right beside the transmitter, tune the tansmitter until you hear the signal you are looking for. Even when you get a signal, you might try tuning the transmitter all between it's limits just in case a harmonic signal is what you found at first. Go with the strongest signal.

Now start moving the radio away from the transmitter. At some point, the signal will become weaker, eventually going away - and if it doesn't, your doing great.

If not, you need to lengthen the wire. There are some legal limits to this, and I think that they are around 5 feet or so. Someone else might be able to chime in here if they know exactly.

Some misc stuff:

The transmitter circuit may change frequency as you move toward or away from it. Putting metal between you and the circuit can help, although

with some adjustment, you can predict how much change there will be and accommodate the problem.

If you aren't getting anything with a short wire antenna and the radio right beside the transmitter, the transmitter probably isn't working.

Our local fire station would like us to provide an HF station to be operated by hams during an emergencies. They have offered to pay the cost of this. We already have an VHF station there. The problem is the antenna. It cannot be visible (or at least not be at all obvious; they are allowing the VHF antenna on the roof now.). The most likely needed band is 75/80 meters, for in-state communications. So we need high-angle radiation, and a vertical does not seem to be a good choice.

The roof is metal, so putting an antenna in the attic will not work. The building is a fairly large 2 or 3 story structure, and in the country with no other buildings nearby.

Here are some ideas I have:

1, A horizontal loop, running all around the building up near the top, but somewhat below the metal roof. Would likely be non-resonant, although perhaps we could choose the length. Mount it on stand-off insulators just off the wooden siding. Use white insulated wire and paint all hardware white, to blend in with the white siding. Feed it at some convenient point, perhaps with a 4:1 balun and then coax into the building. Open wire feed would be better, but we cannot get that into the building and down to the station. Use a coax antenna tuner in the station. The SWR would not be good, but the losses of RG/8 at 75M are not that high. Maybe we could use some kind of outdoor automatic tuner directly connected to the antenna, but I don't know of any offhand.

2. Use the rain gutters as an antenna. I did this long ago in a house and it worked fairly well on 40M. Bridge all the joints with copper braid, painted white, to endure reliable connections. At one of the corner downspouts near the ground, connect the center conductor of a coax cable to the downspout. Bury radials extending out from the building an appropriate length, in a 270 degree sector, and connect to the shield.
I don't know if the gutters are connected to the metal roof, but if so that might or might not rule out this approach. Use a coax antenna tuner in the station. I know this is basically a top-loaded vertical antenna, but the choices are limited.

Comments on both these ideas, and other alternative suggestions, would be greatly appreciated.

73,

Bob W8ERD

thanks mr. coslo, that was very helpful.

i'm sorry to keep bothering you all, but is there any other kind of antenna that i can legally build that will allow me to transmit my signal across the room, or is a simple piece of wire my best bet? see, i don't know a whole lot about antenna construction, so what i mean is will another type of antenna, such as the loop stick antenna, give me better rececption across the room?

does anyone know of any website(s) where i can learn the construction and uses of differnt types of antennas?

How about a 1/4 wave radiator, sloping down from the roof, with the shield
of the coax connected to the metal roof. It would take some trimming. If you
use black insulated wire, it will be almost invisible.

Hi Bob

I guess one should ask how big the roof is... Be handy for modeling the thing.

Since you probably want a set and forget installation with no tuning needed across the 80m (or other) bands, it may be worthwhile looking to a resistive terminated antenna rather than trying to make it resonant/low Z by its size. Kind of like a TFDP but maybe a loop construction using very thin (say) stainless steel wire. I would guess that a balun would still be needed but by playing with a terminating resistor you may be able to make it multiband. Perhaps running around the edges of the roof above the gutter line wont be very visible.

Does the fire station have one of those hose drying towers? I realize you want NVIS rather than vertical pol low angle but it may be worth considering that avenue.

I guess a roof mounted DDRR would be too visible..

A magloop can be small but there might be an efficiency issue there.

A balloon lifted antenna only for use during emergencies or exercises?

If the building is indeed way out in the country are there any trees within a few 100 yards? Perhaps some underground coax to an antenna structure would do it. Cecil has this interesting design at http://www.w5dxp.com/notuner.htm that uses ribbon cable switched in and out for the bands you want to use. This switching could be remoted with the use of relays.

Apologies for not being too specific..

Cheers Bob W5/VK2YQA

It doesn't really matter what the amateur world thinks of it,
I have done my bit in sharing with the ham community
and they have shown me their level of competance and civility.
in return
So I can now move on satrsfied that I truly tried and was rejected
and present it to academia where there are many qualified who
will judge in a academic manner I think then you will regret the
position you have taken as others will.
It has already been examined by a qualified engineer in the subject
and confirmed that the underlying theme as being valid using other
measurement systems which I personaly am not privy to.
So I feel confident that when I put a page on the web next week
tho it will be in rough laymans terms of someone not skilled in the
arts there will be many that will push that sort of thing aside and

delve a bit deeper to get at the essence of what I present.
With that said I will now leave this parrticular thread as it is
now totally off topic.

It seems to me that a simple dipole would work fine or an inverted V. All the fire stations I know of already have a tower of some kind to place the feed point.
All you would need is about 66' of wire off each side slopeing toward the ground at the ends (to make it more omnidirectional)
Black stealth wire comes to mind. The wireman sells it online (just google thewireman) It is very hard to see.
Or you could buy a pre-made dipole for 75 / 80 meters.

My 2 cents.

Joe

>Our local fire station would like us to provide an HF station to be
>operated by hams during an emergencies.

Emergencies? You mean like in the case of a disaster such as a tornado in your community , you might be called upon to provide communications that could save peoples lives and property? You mean, you may be able to provide a communications link to other government agencies in your state when all other ones fail? This is impressive, and this is a great responsibility and you are to be commended for accepting such a responsibility, and providing such a service to your fellow citizens.
Now you need to lay the law down to your fellow citizens/politicians/firefighters. You need an antenna. It requires a support, such as a 30-40 ft tower, one that will survive whatever disasters you forsee, such as wind storms, floods, snow/ice storms (no, it will not survive a direct tornado hit, we all know that). It needs to be vandal-proof, not climbable by kids, etc. You can tell them it will have 2 simple wires running off of it and will look like an letter vee upside down. You can tell them not to waste your time because they are not serious about saving peoples lives if they expect you to do such Mickey Mouse things as loading up the rain gutters, disguising wire antennas around the roof of the building, or any other such foolishness. An antenna that will do what they expect is 2 simple pieces of wire 65 feet long connected to some coax cable suspended 30-40 feet in the air. Tell them if they handcuff you into doing anything else they really weren't serious in the first place. Aesthetics have no place when we are talking about saving peoples lives. Imagine if you were ever called to put into action your ham station, and firefighters were standing behind you looking over your shoulder, and you couldn't be heard because the the friggin rain gutter wouldn't load up. Give me a break.

That was my exect thoughts. If they want to save lives and be prepared for an emergency thye should provide a way to support a wire abotu 130 feet long fed in the middle with a piece of rg-8 type coax. If not tell them to forget it and take your VHF antenna and equipment with you.

Someone mentioned a DDRR on the roof. That may work ok, but the bandwidth is very narrow on 75 meters and can cause problems when you may need to change frequencies.

What type of antenna system are they using for the fire trucks ?
It may be like it is here, there is not much communications gear at the station, but a central dispatch point for several stations. You may need to do something like that and put the HF station at another location.

Ok. I have been watching the discussion on this thread for a while now.
Some people have attempted to help, others just wasted band width.

The situation is that you want to do a demonstration that involves
transmitting a signal and receiving it.

FCC part 15 regulations specify that a low power am transmitter can not
exceed a very low power level (I don't remember off hand how much) and
the antenna must be attached to the transmitter and must not exceed
about 5 or 6 feet.

Any am transmitter that meets these limitations will function in the
manner you desire to exhibit. Any am receiver will detect the signal
from the transmitter over a distance of 50 to several hundred feet.
There are many suppliers of these devices.

Just do a Google search for "Part 15 Transmitters" and you will find
more than you can use. Siple receivers can be obtained from similar sources.

I do not know what you intend to do but don't concern your self to much
on finding the electronic equipment you need, it is readly available and
fairly inexpensive.

Good Luck

Thank you mr. kelly for trying to help me out, but obviously richard is too hostile to want someone else, even a kid, to learn anything about radio engineering. [you know, since he probably never tinkered with electronics when he was a kid and asked someone for advice] = sarcasm

i'm slightly disappointed in him. a grown man, who attacks eager to learn children over the internet. do you not have friends? a life?

besides if you don't help people, but instead show them hostility, don't you think they may become discouraged? maybe even give it up and quit? if there is no one interested in this type of engineering, then it may cease to exist.

all i'm saying is, be an encourager, help others, and go with god.

Taylor wrote:
"I`m working on a science fair project. I`m building an am-radio transmitter. I can only be a few inches from the receiver. --------"

The information is sparse but may be enough.

Kits are available for low-powered transmitters which are restricted by law to a short wire antenna to avoid harmful interference.

My experience is that this is adequate. The receiving antenna is almost unrestricted. It may extend to closely couple with the transmitting antenna, though this is rarely required.

Most receivers are capable of receiving a very weak signal which means the receiving antenna can be distant from the transmitting antenna.

A transmitted signal propagating in free space loses 22 dB in its first wavelength of travel from the transmitting antenna, 300 meters at 1 MHz, and then loses an additional 6 dB every time the distance from the transmitting antenna doubles after that.

So, the tiny phono oscillator with almost no antenna can be heard at a considerable distance.

Best regards, Richard Harrison, KB5WZI

A local fire dept will probably want regional communications within a
few hundred miles rather than DX and this would usually be on 80/60/40m
bands. Since the roof is metal, an ideal NVIS antenna for regional
communications would be a dipole type suspended 20-30ft above the metal
roof. To keep it simple, a T2FD type antenna would not require any
tuning or thought, just plug in and talk. B&W makes a commercial T2FD
style, model BWD-90. I know someone will chime in and say these are crap
but they work just fine and I believe a slight trade off in performance
for ease of use is paramount for the situation you describe.

Ive found that carboard tubes soaked with fibeglass resin make a good boom for small antennas. I have a friend that builds boats that will give me small quantities of fiberglass resin from time to time so expense of the resin is no problem for me.

Good morning, Bob.

Yeah, good luck with that.

T2FD antennas can exhibit as much as 17 db of loss while maintaining a decent VSWR.

I have run communications tests with another amateur who lives one town away. We have similar grounds, similar HAAT, and similar height AMSL. He uses a B&W T2FD antenna (I believe it's the B&W-90) and I use a cut dipole for 75 meters, at comparable heights (mine is 17 feet high and his is something like 25 feet I think). He runs 100 watts and I run a grand total of FIVE (5) watts with a Yaesu FT-817. I often get BETTER signal reports on 75 meters than he does, from stations within about a 100 mile radius of here.

I certainly wouldn't want a T2FD antenna for mission-critical use, especially since for the price of a B&W, you could buy an auto-tuner from LDG and have just about enough money left over to cover the materials for a cut dipole.

Because i need 180 deg coverage i have to use both antennas together.
The 3dB beamwidth of 90deg of both antennas give me 180deg coverage.
And i expect the gain to be 3dB down at 90deg but instead i am getting
gain less by 10 to 15 dB. Is there any way i can get less ripple at
the overlap?

wrote:

>I hope it helps the student with his science project.

Hi Dave,

That is of infinite improbability. How many times do we have to tell
adult amateur radio enthusiasts the necessity of matching (a warning
already offered from the shadows of this thread)?

So, shall we consider the merit of a total length of 3 meters in the
AM band? If this discussion is so studiously avoided by those who
weep away about the dearth of information, what chance does a naive
student have to rummage up the details?

The Rr summons up to roughly 20mOhms. Are any of the scolds going to
offer the implications of this value? Are there any suggestions of
using commercial tower sections to cut down on Ohmic loss? Any
matching details for the massive SWR? Any hints on how to load the
structure? Details for a top hat? Would the top hat consume part of
that 3 meter restriction?

Would a loop perform better? What dimensions? How to build the
capacitors? Talk about underwhelming help....

>the dark side of the net had to have it's way with the subject.

The dark side is not patronizing with soothing but impotent nostrums.
The topic reduces to one of two resolutions:
1. Deep consideration of many issues;
2. Buy a kit that works as advertised.
One takes many here a lifetime of consideration and books are devoted
to this study, the other satisfies a need.

> the overlap?

Hi Rohit

I think this "pattern merging" will become clear to you when you consider the fact that the signals from each element has equal amplitude at Crossover (90 degrees). Therefore the signal at that direction will add to twice the value of either, ir subtract to zero, depending on their phase. That is a heck of a big difference from In Phase to Out of Phase.

I'd suggest that you include more info about your ultimate goal. There are some very well informed guys reading this news group who might be willing to help you.

Source record: 45971

The B&W BWD90 is about 5-6dB down from a dipole on 40m and up and 80m
and down does suffer more loss thatï¿½s true. If there is room for the
180ft version it should have consistent performance down to 80m. If you
try to feed a mono band dipole with coax and an LDG tuner it will
probably have more loss on some bands than a T2FD and using a 4:1 balun
and balanced line is better with an LDG but it will not tune everywhere.
Whatï¿½s worse, an antenna that will not reliably tune where you need it
or an antenna that will always work with some loss? You have to consider
the user in this case as someone who may not have the experience to
diddle with tuners or recognize when something is not working properly.
Not everyone can make reliable contacts with an FT-817, it requires
knowledge, patience and higher efficiency antennas. If it were up to me
to set up a fire station for regional comms, I would consider the 180ft
B&W, a simple to use HF rig and a solid state 500w amp which will make
up for the 5-6dB loss of the antenna over a dipole when necessary. And
that is assuming a resonant dipole at low height is my design goal.
Also, 1000ï¿½s of B&W T2FD type antennas in use right now working just
fine in military and government use for there intended purpose, which is
push the button and get the message through without messing around.

I remain puzzled why you guys are discussing compromise antennas in an emergency communications system. I wonder if the fire department guys built a compromise VHF/UHF communications system when they spec'd out their requirements and performance. Did they hide their 154 MHz antennas under the roof? Did they look for a means to "just get by?" Did they mount a rubber ducky, with a gutter clip on the backside of the firehouse under the rain gutter, and connect it with RG-58 to their radio?
If this is a for-real emergency communications solution that the community desires, and they have asked amateur radio operators to be prepared (that is truly an honor) then don't we hams owe it to the community and our own reputation to build them a station, with antenna, that WORKS, that puts out a solid, dependable signal?

news:1170863623.642498.284210@h3g2000cwc.googlegroups.com...
>>This will be the last word I have on this topic.<<

As: This is the last word from the higher authority, like, no more arguments, I am right, case closed? Just in case you might be wrong, here we go:-)

>>I have placed two files here:
www.k6mhe.com/n7ws/N7WS_Yagi_Resonant.EZ
and here:
www.k6mhe.com/n7ws/N7WS_Yagi_Shortened.EZ
The files are models of my 20-meter three-element Yagi that are as nearly representative of the physical antenna and its location as I can make them. The only difference between them is the half-length of the DE. The actual antenna uses the shortened version with a stub (Beta) matching/balun arrangement.<<

What you mean half length of DE?
Resonant DE is 410.68" long
Shortened DE is 399.64" long - that is 11.04" difference
Resonant frequency on resonant model is 14.18 and shortened is 14.48

>>Instead of the integral stub, which Yuri believes is part of the antenna that is "folded back" along the boom, I will move the matching system away from this location using an ideal ¼ wavelength (34.7 foot) transmission line with an ideal current balun at the antenna end. I don't believe anyone would argue that the feedpoint impedance is not replicated exactly at the input end of this line.<<

Yuri believes? Is anyone there who does not believe that hairpin loading stub or beta match stub inserted in the middle of driven element is not the part of the element, aka, standing wave resonant circuit? Like there is no RF current flowing into the hairpin? Like element does not have to be shortened to compensate for the insertion of the stub? Doesn't Yagi antenna work with half wave (+-) resonant elements? If you loaded, inserted stubs in the parasitic elements, you would not have to shorten them?

>>"Calculations" proving ??? snipped<<

>> The network loss remains 0.02 dB. So much for this less than ideal stub vs. Yuri's preferred discrete inductor.

There you have it. The stub matching method is equal to a discrete L-network in efficiency, it does not detract from the antenna efficiency one bit, it can incorporate the balun function without additional

components, it grounds the feedpoint, with a little sealant on the cable, it is weatherproof and unlike Gammas and Tee-matches, it will handle full power without being prone to capacitor breakdown. It is not part of the radiator; it is part of the matching network. Period.<<

Claiming that beta match or hairpin loading inductance is not the part of the radiator is news to me.
Claiming that driven element was shortened to half, when in fact just by 11" and resonant frequency moved from abt 14.18 to 14.48 MHz, and modeling the antenna without the beta match hair pin, and then "calculating" 0.02 dB difference in gain, sure "proves" the point.

Here I described the real life situation and modeling by using simple case of 40m dipole, resonant and resonant shortened with "beta match" hairpin. I maintain the resonant frequency and compensate for the effects of inserting the hairpin. The gain on the dipole drops by 0.15 dB when fed at the 75 ohm point and by 0.2 dB when fed close to 50 ohm point. You can read the rest at my web site:
http://www.k3bu.us/beta_match.htm

Again, it has ben proven by modeling and in practice that loading solenoid coils are better performers as loading element than hairpins, especially when better symetry along the element is important for bettern pattern and F/B. But I guess, that's another story to argue.

Not the last word from me, if I am wrong and made error in modeling, I would like to be corrected. (I tried to post the EZNEC files, but having problem downloading them. Will try to rectify.)

After re-reading the original post I see the fire dept system will be manned by experienced hams and that would allow for more complex but efficient equipment like antenna tuners and antennas fed with balanced line, etc. Even a G5RV with a tuner might be something to consider. One thing I will point out would be the compromise if someone installed a vertical like an R-7 or GAP Titan or Butternut, etc for regional or statewide comms. The difference between a T2FD and resonant dipole would seem like nothing compared to a T2FD over a vertical for this type use.

I couldn't agree more. I suggest you go back to fire depatrment and
ask which they would rather have 1) an efficient and good working
communications system or 2) a small non-noticable antenna that
performs poorly. You can't give 'em both.

The "distortion" you're seeing is the sum of the fields from the two antennas, which vectorally add to produce a total pattern. This is a "phased array". The pattern of a phased array depends on the relative phase and magnitude of currents in the elements (in your case, the antennas), the spacing between elements, and their relative orientations. So if you don't want to change antenna positions, the only alternative is to alter the relative magnitude and/or phase of the currents in the two. One source of information about this topic is Chapter 8 of the _ARRL Antenna Book_.

Good morning, Bob.

That's true, and that's why I wouldn't do that ... as you noted later, I'd use ladder line and a balun.

> What's worse, an antenna that will not reliably tune where you need it
> or an antenna that will always work with some loss?

I don't know, depends on WHERE and to what extent the cut dipole would fail to reliably tune. Anyway, that should be handled in the design of the antenna, which of course needs to be done by somebody that knows what he/she is doing. I assume that the fire department that is the subject of this thread knows what frequency range(s) they need the HF station to cover. Design the antenna and autotumer combination so that it tunes efficiently across those frequency ranges

> You have to consider
> the user in this case as someone who may not have the experience to
> diddle with tuners

That's why I suggest an autotuner.

> or recognize when something is not working properly.

That's an issue with any installation. You could have any antenna you can imagine, and something could go wrong making it "not work properly". There needs to be someone around who has the skills and experience to recognize that.

> If it were up to me
> to set up a fire station for regional comms, I would consider the 180ft

What if your emergency installation has to operate for extended periods of time on emergency power and you need to conserve power? That power-hungry 500-watt amplifier may not be especially welcome in that case.

Anyway, I could put up at least three (or more) cut dipoles with ladder line and autotuners for the price of that amplifier.

> Also, 1000's of B&W T2FD type antennas in use right now working just
> fine in military and government use for there intended purpose, which is

They are working, somewhat, for the most part. I would argue whether they're working "just fine". They're doing the job because (a) the people that installed and use them don't know the difference; and/or (b) they have plenty of your tax dollars to spend on higher-power transmitters to compensate for the antenna inefficiency; and/or (c) they're operating ALE installations that jump around all over the spectrum and, really, the T2FD antennas are all they can use so they have to suck it up and live with the loss.

On Sun, 11 Feb 2007 03:01:13 +0000, Bob wrote:

> Even a G5RV with a tuner might be something to consider.

One thing you need to keep in mind is whether even 75 meters will be sufficient for statewide communications around the clock. I can tell you that often it is not. Around here, in the wintertime the critical frequency (the maximum frequency at which a signal arriving straight up will bounce back) falls to well below the 80 meter band at night. Often the critical frequency will be around 2.5 MHz, or lower, by around 10 PM. During those times, your 75-meter NVIS signal will just go sailing off merrily into space. You have to be on 160 meters during those times, if you want reliable NVIS communications.

I am a regular participant in a military traffic net (not MARS, but similar) that operates at 0730 each morning, on a frequency that's not so very far off the high end of the 75-meter band. The normal net control station is about 80 miles from here, and in the wintertime, the critical frequency is often right around our operating frequency and rising fast as the sun comes up. Very often, I can just barely hear the NCS (or can't hear it at all) at net starting time of 0730, but by 0745 to 0800 the NCS has come up in strength to where solid 100 percent copy is easy. Move the net start time to a half hour earlier and there'd be no way... we'd all be talking to ourselves.

As for later in the daylight hours, 75 meter signals often get absorbed by the D and E layers so they never bounce back. During those times 40 meters is your only hope.

So, for an emergency station that has a snowball's chance of being able to maintain communications 24x7, you need 160, 80, and 40 meter coverage from an antenna around 30 feet high if you can get it up that high. That would be the low end of the best height range for 160 meters and the high end of the best height range for 40 meters.

Suggest that you print my graphic, and look for different heights of the transmit and receive antennas that still clear the 80 meter hill by using a straight edge that always crosses the location of the hill at the elevations shown in my plot.

It is best to provide more path clearance at the 80 meter hill than I showed, because some K-factor variations could steer that 10 GHz beam into that hill, and cause loss of a usable signal for the receiver.

Also remember that this plot was done over a smooth earth. The true elevations at the endpoints of the path and at the hill could be considerably different than I showed.

I use a version of a fan dipole on HF.

It differs from the standard fan in that the wires are hanging under each other with the longest wire on top. There separated 12" apart, the first one being close to the feed point.
The 3 wires are cut for 20m 40m and 80m. With a good tuner it will tune any band from 10m and even a bit of 160m close to 1.8mhz.

One good thing about it is...

After it was tuned, I measured everything. If a storm or such takes it down it can be replaced very quickly.
It is also hard to see unless you are looking for it.

My 2 cents

It would be simpler to just attach a resistor. That much cable is
going to be so lossy that any useful signal going in will never see
the other end.

The solution is to use 40ft of Cat9 to extend the wireless router.

OK - thank you. I think I need what is called a pigtail; but at a price. And - yes - I think the cable will be too lossy. I'll research the cat9 solution suggested. Thanks. Or I'll just have to buy a Linksys Range Extender at £100+. Unfortunately the guys at Maplin hadn't a clue on how to advise me. Actually I might just be able to use a 40ft phone extension cable and use a modem instead of WiFi. The WiFi sgnal is just too weak to go though 5 brick walls!! Thanks again - Chris Brady.

CJB;

Before you invest to much more time and money in your project, no matter how necessary it may be, you need to look at the signal loss generated by the RG174 you are proposing to use. It is so extreme only very short lengths should be used, 1" to 3'.
A better suggestion would be to purchase a range extender that is available from most vendors of broadband equipment such as Best Buy and CDW to name two.

RG174 would be a very poor choice.

LMR195 (RG58 dimensions) is more likely to be the type of cable used for
small diameter, or larger LMR types for a long run like 40'.

The loss in 40' of LMR195 at 2400MHz is ~8dB, not a pretty picture. Losses
in a metre or three are practical.

Owen;

I just picked on RG 174 as an example. Your choice is not very much
better which only points out the problem with coax at high frequencies.
I think that the original writer has decided on his own to do something
else.

Thanks guys for your help.

The exact problem is that I use two flats in the same block - one for living in, and one for work - on the same floor - but separated by a long corridor. The WiFi signal gets half-way along the corridor and then disappears. My phone socket and WiFi router (and printers) are all is in the work flat. I'd like to use the PC in my living flat. But there is no WiFi signal there.

But I've actually been beaten by not being able to attach the SMA connectors to the coax - too fiddly!! £5 down the drain I guess.

I may have an alternative - that is to use a 80 ft. long extension cable from my phone socket in my work flat to a modem in my living flat. I can route the cable down the corridor above the false ceiling panels. WiFi I can use when my PC is local to the router. Hmm - kind of contradicts the use of WiFi but the signal is too weak anyway. Incidentally I've tried tweaking the RF power output, but its set on maximum anyway.

Unfortunately an intermediate Linksys Range Extender / Relay will not work because I do not have a power supply for it in the corridor mid-way between where the router and phone socket are and where the PC will be used.

Hi Chris

Dont feel bad about not being able to work on those SMAs. They are difficult both because of their small size, and their gender changes from application to application.
There is *no* way I would consider wireless if the CAT 5 is a valid choice for interconnecting computers.

Jerry

>Just found a possible solution:

Only if both flats can take the 5dB loss in the cable, AND the path
loss of 4.5 meters. Wireless routers are rated for quite a distance
in the clear, but apparently your brick puts the challenge to that.

Walk down the hall with your laptop running its adapter program
showing signal strength. How far can you go? If it isn't half way,
you don't stand a chance. If you can, then subtract 5dB (which means
roughly to the other flat's front door) and the signal should still be
substantial (or your throughput will plummet).

Run CAT5 between flats and buy another router.

Dear Bob:

It is nice to hear from another of W8JK's boys.

You have received some good ideas and discussion.

Having dealt with the underlining need you described, the technical issues usually turn out to be minor as compared to the people issues. What you are likely most to need is a sharp people-person who can uncover what the real reasons are for the apparent need for invisibility. Once you know what the actual issue is, you can work to optimize the system.

You must have the clout, once you understand the people issues, to convince the right people about an effective antenna system.

My preference is a dipole with about 100 feet of wire on each side that is supported in the middle by a 40 foot tower. From the feed point to the base of the tower I would run a piece of solid-outer coax that is heavily choked with surrounding choking-material. At the base, I would attach a commercial auto-tuner and run its coax and control cables (well choked) underground to the station. An embellishment would be a second dipole at right angles (connected to the first dipole) that is resonant around 5.4 MHz. A good fence around the tower is desirable.

Feel free to contact me.

Cat9, hmm, the only Cat9 I know of is -

http://www.tubecollector.org/cat9.htm

and while it's quite lengthy, 40 feet of them would not be suitable for
use at microwave frequencies.

Perhaps you meant Cat5. ;)

It is a neat tube though.

Source record: 46000

given that the length of a half wave dipole is
calculated by 468 / freq in mhz when velocity factor
is 1, ie 468 / 1.9 is about 246 ft.

i'm sitting here wondering why folks with small
city lots don't use (468 / freq in mhz) * velocity factor,
to construct a much shorter antnenna, particularly on
80m & 160m?

as an example, rg59 coax typically has a velocity
factor of .66, so plugging to the formula,
468 / 1.9 is about 246 ft, * .66 is about 162 ft.

why couldn't 162 ft of rg59 be cut in two, attached
to a 50 ohm, have the remaining ends of the rg59 shorted
together, and hoisted into the air?

so what am i missing? there are no free lunches:-)

The velocity factor of the inside of RG-59 is 0.66
when the currents are differential. The inside of RG-59
doesn't radiate when the currents are differential.

The outside of RG-59 is used for radiation. The velocity
factor of the outside of RG-59 is about 0.95, about the
same as ordinary insulated wire.

One wavelength in free space in feet is 984/F in feet (300/F in meters); a half-wavelength is 492/F. 468/F assumes a vf of 0.95 of the antenna radiating surface.
The vf of coaxial cable is dependent upon the dielectric used. 0.66 is common for solid polyethylene. Foamed PE is typically near 0.80. As with many RG cables, RG59 is available both ways.

In your example, the vf of the dielectric would not matter, since the majority of the current flows on the *outside* of the shield due to skin-effect. Thus, the formula for the length would be very close to (only slightly shorter than) 468/F. Since I^2*R losses would be lower, bandwidth would be better than a smaller-diameter wire.

The LMR195 is 12.4dB better, I will leave it to the end user to make his
mind up about whether that is "not very much better".

Yes, clearly the message is to minimise the length of RF transmission
lines, and to use line types appropriate to the length and application.

dropout rate was quite high. But I did get about halfway along before
the signal was lost!!

I did a Google on the web for 'Cat9 cable' and did find some mention.
Also for Cat5.

I'll see if the extension cable works. But might be resigned to a
repeater halfway along the corridor. I could hide this in the ceiling
panelling and power it with a cable from either flat!!

There is another solution - maybe - to attach a full size indoor
aerial to the laptop. It has a t.v. card in it!! Maybe that would
increase the strength of the input signal to the wireless card.

My previous ISP sold me off to a new one. SInce that time I've had no
end of email problems and in addition the new guys don't provide
newsgroups, so I've been reduced to using Google Groups. Yuch.

I spent too much time composing a response to Yuri's last post and
then did not see it appear after posting. I will not waste further
time, but in a nutshell I offered another case using the self-
reactance of the DE as part of the matching network.

In this example, to avoid any "loss due to loading" resulting from
shortening the DE, I *lengthen* the DE to obtain an inductive
reactance for the series arm of an L-network and then use a shunt
capacitor for the second matching element.

The model is here:

http://www.k6mhe.com/n7ws/N7WS_Yagi_Lengthened.EZ

Run the analysis, and add a shunt 195 pF and see what you get.

Hi Chris

You might want to test the data transfer speed while making your "distance tests". I'd use CAT 5 whenever the cable connection can be allowed.

Hi Andy

The TV antennas with the V shaped elements arent Yagi antennas. Log
periodic V antennas are fed from their "front end" to produce a minimum
toward the rear.
A TV Yagi antenna is good for any one channel. A LPV antenna is good
for all the channels but not as good for the one channel the yagi tunes to.
The LPV elements are slanted to an angle where their radiation pattern
adds in the Forward direction when they are a 3/2 WL dipole.

To achieve resonance in a shorter antenna, you can increase either the capacitance or the inductance--or both, of course. To increase the capacitance, all you have to do is fill the universe with polyethylene, or some similar low-loss dielectric. You don't have to actually fill the whole universe with it; it would work to fill a volume around the antenna. But to get the full effect, it should be a pretty large volume, containing the electric field in the neighborhood of the antenna. Not very practical. In coax, the electric field is between the wires; in the dipole, it's also between the wires, but the volume is very much larger. On the other hand, people have been shortening resonant antennas for a long time by increasing the inductance: thus, loading coils and "slinky" antennas. Similarly, people make "slow" coax by making the center conductor a helix, and thus make delay lines.

Cheers,
Tom

So what you're saying is that although you could explain how to make a loopstick antenna resonate at 1 MHz and properly couple it to a crystal oscillator circuit, you feel that someone else should do it for you.

Hi,
What's all this business I hear people talking about blasting people's car stereos or killing cars altogether with high-power RF? I run 2m, 10m, and 11m in my jeep and I'd like to sort out the fact from the legend and find out what kind of power I can use without risking damage to my jeep or cars around me. At what power level is front-end overload to a nearby radio likely? At what power level is damage likely, and to what componets?

I am currently using only 50 watts on a 5/8 wave (2m), 25w on a 1/4 wave (10m), legal 4w on a 1/4 wave (11m)

Thanks,
Nelson KE5MBX

I think over 100W you may have problems with HF and VHF. It can be a
problem.

One thing that works real well is to transmit near the x-ray radar band
where you have privileges. The traffic may slow down a bit as you set off
the radar detectors :-)

It doesn't take much. Back in the early '90s a group of us were returning from a hamfest and I was riding in the back seat of one guy's late '80s Ford something or other (Crown Victoria, maybe?). I was using my HT to talk to the other car on 2m and the driver noticed that his cruise control was gaining speed and when I unkeyed it settled down. Once I figured out it was my HT causing it, loads of fun ensued.

If something is sensitive to RF, it probably won't take much to cause it to malfunction. The fact is that nobody does RF shielding or protection for consumer electronics, so there is no set power limit below which a device may not be affected.

Source record: 46019

Looks like W8JI type of response: I am right, I will not respond to questions and arguments and my is last word!"

Fact 1. - When hairpin or beta match is inserted in the driven element or any resonant half wave dipole, it has current flowing through it.

Fact 2. That element has to be shortened if resonance is to be maintained, which means that it is a center inductive loading element, hairpin, beta match is the part of the antenna standing wave circuit.

Fact 3. There is current that would more, less belong to the antenna element flowing in the hairpin, folded on itself and on right angle to driven element, not contributing to overall current distribution. That can be seen in my EZNEC model in the article. That portion of the current is not in line with the rest of the element, it is missing from as to compared to full size element and therefore efficiency is slightly lower (middle part of the cosine wave is "missing" folded with hairpin). On typical 40m dipole, as I modeled, it accounts for about 0.2 dB loss.

The original argument was is the beta match lossy or not.
My modeling of the real situation is ignored, also findings and experimental verification of others who replaced hairpins with solenoid coils is ignored.
What you are "arguing" is that if you place the matching network in the driven element (now you even lengthen it) that there is no loss.
http://www.k3bu.us/beta_match.htm
Is my modeling of 40m dipole wrong? Where? On dipole it shows about 0.2 dB loss, which gets bit more when used in multielement array.

If you are denying that there is a RF antenna current flowing in the Beta match hairpin, then you are denying reality and I rest my case. No point of arguing or discussing when you do not show where I am wrong, but you offer "proof" by juggling matching components at the feedpoint. We are talking about hairpin that is part of the antenna element, has current flowing in the system and it has feedline attached at the feedpoint of element and hairpin. No tricks with coils or capacitors inserted half wave somewhere.

73 Yuri, K3BU.us

We are not arguing loss due to loading, we are arguing - does hairpin beta match contribute to the loss in the system or not.
I mentioned that there are better alternatives, if one choses to be less lossy.

Back in the '70s I was working on a project that saw me reading papers on the effects of EMR on various things. Amongst the papers was one dealing with the susceptibility of the electronic anti-skid technology introduced on heavy transport vehicles to meet (then) newer more stingent braking distances. The braking systems were susceptible to ingress of RF, resulting in wheel lockups. You can imagine the results of a 22 wheeler at highway speed when a chook alongside comes up with "Breaker, Breaker, any taker?" and locks up most of the wheels on the transport. I read other papers on rear wheel lockups in a certain brand of passenger vehicle due to RF induced downshift of the (electronically controlled) automatic transmission at highway speeds.

The EMC issue seems better understood by vehicle manufacturers today, though you still hear of RF triggered airbag deployments from time to time.

I won't go into the papers on effects on aircraft, some of you may fly from time to time! A paper on propagation of EM waves through rectangular slots in thin sheet metal looks innocuous enough until you realise that it is talking about an aircraft window (in the days when almost all aircraft had a metal skin).

Owen

1358. Re: killing cars with high RF?

Source record: 46022

Dear Owen: Well do I remember the onset of EMC awareness that came with the early anti-skid systems. One horror case took place in Chicago with a bus. One of the many short bridges in Chicago has metal decking and a bus stop at the far end of the bridge. The bridge also is aligned with the Sears tower (in downtown Chicago it is difficult not to be aligned with some strong RF radiator - it is worse than a carrier). Bus starts onto the bridge. Patrons stand to get off at the next stop. Breaks fail while on bridge. Driver fully asserts the brakes. Bus arrives at the end of the bridge and the brakes start to work. People go flying.

I was a witness of the (very early and crude) method used to test systems. Not anymore! Today, whole cars are zapped from all directions, all frequencies, and at huge amplitudes. A huge effort was made to find out what sort of signals a car might encounter. I once rode in a van all the way to Chicago glued to a SA to record strong signals. The worst that I saw was a VOR signal (few hundred watts at ground level with a very good radial screen and near the road) and a CB signal. Others in the project measured at VOA and LORAN sites. An FM broadcast antenna was found to radiate a huge signal onto a public street - see, you know that antenna design would be worked into the discussion - in this case an incompetent, but not unusual, antenna design.

At work, we have a big RF amplifier used to zap devices in order to find out where they die. Had to get a waiver from FCC because, even though the amp requires three-phase, it could be used on 27 MHz.

Critical equipment is much more EMC capable today.

you might have more issues with RF exposure to you and safety,
particularly on the 2m band, depending on where the antenna is.

But, as far as killing your car radio (or one next to you) goes, you'd
have to look at the coupling from your antenna to the car radio's. 2m
is going to be the worst case because the victim receiver is close to
that frequency, so the coupling from your antenna to its is highest.
The easy case is the car in the next lane (because it's reasonably far
away.. more than a couple wavelengths), so you could do some sort of
rule of thumb free space path loss kind of calculation...Say you're 5m
away at 144MHz.

Loss = 32.44 + 20*log10(d in km) + 20*log10(f in MHz) = 32.44 -46+43
dB = about 30 dB loss. You're radiating 50 W, and let's assume your
antenna is 3dBi, so your EIRP is 100W or +50dBm. The victim is seeing
+20dBm (a tenth of a watt)... about 2 Volts into a 75 ohm load.
Assuming the victim radio has protection diodes across the input,
you're probably not going to kill it. Run a kilowatt and it's another
story...

As a practical matter, my 2m antenna is about 1 meter from the car
radio antenna, and when I transmit at 50W, the FM car radio blocks,
but recovers just fine. Likewise, transmitting at 100W on HF. Your
mileage may vary, etc.

10.525 GHz is an amateur band, and is the same band used by the X-band
radars, and transmitters are readily available for <$100. Gunnplexers
are one example, but people also use modified "microwave door openers"
to experiment in X band.

The increased prevalence of EMI/EMC problems means that modern cars
are MUCH better about this. Almost all new cars go through a fairly
rigorous test program for immunity from radiated fields. Nobody wants
to have the engine or braking control systems fail when the police car
next to them calls home on their VHF low band radio. There's rafts of
SAE specs for this, but I don't recall the field strengths. Several
hundred volts/m though, is what I think.

Aftermarket addons (stereos, nav systems, etc.) aren't nearly as good
on the account. Some automotive equipment is exempt from Part 15 (for
instance, the nifty OBD II readers are pretty good RFI emitters...)

Normally elements like that would not be used, but if you want to make a
yagi that runs at 1f and 3f, "slanting" the elements allows it to have a
reasonable pattern on triple the normal frequency while not mucking up
how it runs at the 1f too badly. 144 and 432 work fairly well.

If you turn the trick right, the metal in question will work on 6, 2 and 70.

And you can easily do 200KM on 200 mW, or 1000 KM per watt with a Dish Network (or equivalent) antenna on 10G SSB forward scatter.

Well:

Point 1. What is wrong with a W8JI type of response?

Point 2. I already violated my promise to remain silent on this
thread, in the pointless belief that it might be possible to reason
with you. How wrong I am.

>
> Fact 1. - When hairpin or beta match is inserted in the driven element or
> any resonant half wave dipole, it has current flowing through it.

In my "lost" post, I addressed this. I said more-or-less, of course a
stub, hairpin, beta, or whatever you would like to call it has current
in it. If it didn't then it could be removed without effect. So
what? Also if the stub is < 1/4 lambda and shorted then the current
is maximum at the short. Again, so what?

>
> Fact 2. That element has to be shortened if resonance is to be maintained,
> which means that it is a center inductive loading element, hairpin, beta
> match is the part of the antenna standing wave circuit.

How about calling it a point rather than a fact? The real fact is
that when shortened, the DE is no longer resonant.

In an earlier post I said, and you apparently chose to ignore it or
were too busy formulating a response to read:

"Instead of the integral stub, which Yuri believes is part of the
antenna that is "folded back" along the boom, I will move the matching
system away from this location using an ideal ½ wavelength (34.7 foot)
transmission line with an ideal current balun at the antenna end. I
don't believe anyone would argue that the feedpoint impedance is not
replicated exactly at the input end of this line. "

Now when the hairpin, beta, or lumped inductor is 1/2 lambda away from
the DE and it acts *exactly* the same, are you telling me that it is
still part of the radiator and "loads" the DE?

If you are saying yes, then this discussion really is over. If you
will keep an open mind, let's say to keep the numbers easy, that the
DE feedpoint when shortened appropriately is 25 -j25.

At the input to an ideal 1/2 wavelength line, terminated with the DE,
we will also see 25 -j25. The parallel equivalent of this (I should
use admittences, but I'll leave it as impedance) is 50 || -j50.
Shunting this with an inductive reactance +j 50 results in 50 +j0, or
a perfect match.

Now I suppose it can be argued that this is "resonating" the DE,
although I would prefer to say the system is resonant.

I don't see how you can argue that the added inductor is "radiating"
or "subtracting" from the radiation of the DE, or whatever your point
is.

Nevertheless, you give it a try below. But I'm not sure Google is
going to post this anyway, so I'm stopping here. I think the OP's
original question has been answered: For all practical purposes, the
radiation characteristics are unaffected by the matching scheme.

I have done quantitative signal strength measurements professionally, but you don't need any expensive gear to get some decent comparitive measurements during your field exercise.

I would recommend a level-shift technique to determine the relative merits of your systems under test. Doing this only requires a fixed transmitter and a mobile receiver with an S-meter and a variable attenuator. Also, having an independent coordination link is a real plus. Local repeater?

At each of several remote locations, have your transmitter site key up. Next, insert attenuation as required to reduce the S-meter to some chosen low S-meter reading using one of your antennas. Repeat for each antenna. The antenna that required the MOST attenuation is the one pulling in the strongest signal.

I zipped through the foregoing. If you want a more detailed treatment, let me know.

You can't use 40 ft of RG174, but here are some possibilities.

1. Extend the Ethernet cable instead.
2. Use a couple of inches of RG174, then an SMA to N adapter, and 40 feet of LMR400 or Belden 9913. Be advised, either of these is big stuff, about 1/2 inch.
3. Put a high gain yagi antenna on the router end (probably vertically polarized), pointed at where wireless user is. If it works, this will be the cheapest solution.

Wes,
you are ignoring my questions and modeled example showing the situation in question: resonant dipole loaded and with beta match vs. full size straight, reflecting the real life situation in question.

You believe what you want. I have showed dipole element and EZNEC model of effect of beta match on performance of antenna: reduced gain, narrower bandwidth. It shows the current distribution along the element and the hairpin beta match. That current along the beta match is "taken out" of the element and causing reduction in gain and narrower bandwidth. Model shows that and measurements confirm that.

This is just another application of the current along the antenna coil (loading element, hairpin, etc.), its effect on the current distribution along the radiator and corresponding efficiency.

Believe it, or not!

Source record: 45888

Hi all,
With the same setup as i have stated before, I have observed the pattern by changing the spacing between the 2 antennas. For every 1 wavelength increase in spacing i am abserving one lobe around 90deg. As the spacing becomes lage multiple of wavelength, the ripples magnitude increase to greater extent. Can someone explain this. With the experiment i've done, it indicates that for the spacing of 1 wavelength i get the best pattern without ripples.

It is the constructive and destructive mixing of the rf being emitted by your antenna's. Your results are exactly correct. It is the reason that twin cb radio antenna's don't really work on an 8 foot wide truck. At that spacing they are only a fraction of a wave length apart and act as one antenna.

Yes you can. Check the back of QST for a complete 3cm station. Cost is
about $500 or so.

And for the third time, you still ignore part of the hierarchy.

While the first RFD ignored the hierarchy except for .misc and .policy,
and the second RFD added .antennas and .dx, this third RFD long after
the discussion started still ignores three of the newsgroups in
the hierarchy:
rec.radio.amateur.boatanchors
rec.radio.amateur.digital.misc
rec.radio.amateur.space

In the end, you can't speak for the hierarchy if you don't even
know which newsgroups exist in the hierarchy. No wonder you have
such disregard for the hierarchy, you only think of yourself as some
"administrator" type rather than a participant.

You aren't building bridges, you're imposing your vision on the hierarchy.
The fact that you still don't come to the hierarchy and simply talk to us,
isntead hiding behind the structure of creating a new newsgroup, says
everything about your relationship to newsgroups.

IN the end, I conclude that you like moderated newsgroups because Usenet
never sat well with you, and the only way you can deal with it is impose
your need for rules on something that is a haven from that.

Ultimately, you are like the problem posters. Neither of you can live
without rules, though you need them because you can't tolerate the lack of
rules, while they need them because they think the lack of rules is license
to do as they please.

You've spent the decade trying to impose rules on the hierarchy, while
the rest of us were actually trying to make the hierarchy good by
participating in the discussions.

Useless administrators are always trumped by people doing things.

Uh, not quite. While the X Band police radars are at 10.525 GHz, the ham band is only from 10.000 to 10.500 GHz. Plus, pulse modulation is not allowed on the 3cm band. We CAN use MCW, phone, image, RTTY, data, SS, and test modulations. Hmmm, I wonder about plain old vanilla CW??? I don't see it mentioned...maybe "data" covers that nowadays (and with a bandwidth limit of 100 KHz, we could smoke along at a LOT of WPM!!).

Owen is right-- When a radio-man , had a guy come into the shop, complaining about his truck stalling when he transmitted. (freq around 160 MHz) Ran his truck, (idle), keyed rig, NO Problem! Said to take it for test run- in low gear, (abt. 2000-2500 rpm), and keyed the transmitter, the rig STALLED! Wasn't a problem when I installed radio- turned out they had modified the truck to an Electronic Ignition! This around 25 years ago. Tried various cures but, they went back to the original "Points & coil" system and worked fine! (this before these were common on vehicles). Translation: YES, can effect a vehicle, but times have changed: might not be so supsceptable now a days (more problems with the built in computer that they seem to like to hide-- drill a hole in these- turn a car into a thrashing machine!). But BOTH can cause problems. btw the power level for the problem was a 50 Watt radio. and the SECOND problem (think they more standardized now), could be placed as the manufacturers stated, (ANYWHERE in the vehicle) ! Now days must be within 3 foot of the OBD2 Plug (used for smogging)! At least in the U.S. As info, Jim NN7K

CW is almost always used for beaconing to align antennas. SSB is then
often used for the contact, however CW is used if it is marginal. Just
like HF, VHF and UHF contests. The major difference is that the
transmitter will often drift a couple hundred hertz during the QSO. ;)

I have a few audio clips from the 10G cumulative contest last fall. If
anyone is interested I will email you a link.

Also see the article in this months QST by Jon Platt, W0ZQ.

True. One time I was testing VHF antennas at 5 watts output in a quiet
garage. I kept hearing a clicking noise every time I keyed up. I traced
it to an analog multimeter on my bench. I was pegging the poor meter from
about ten feet away.

Source record: 45907

All,

How do you determine the axial ratio from a RHCP wave to a LHCP wave
from an antenna? In essence, I need an axial ratio transformation from
RHCP to LHCP.

Any ideas on the equation or where I can find it will be helpful.

Thanks.

Bobby.

Hi Bobby

If you are working with an antenna that radiates RHCP it is totally
insensitive to LHCP.
If you have an antenna that radiates "RHCP" (or LHCP) the axial ratio is
the ratio of the Minor axis to the Major axis of the E field. So, it
varies from zero to one as the radiated field varies from Linear to
Circular.

Hello Black Sheep,

Can you provide us with some information about your antenna
challenges? It will make us easier to answer your question.

I am thinking of antenna types (wire antennas, printed circuit board
antennas, with / without dielectric materials, size with respect to
wavelength, etc), how frequently will you us it, available budget, is
it for professional or amateur use, etc.

Best Regards,

Wim

Hi Black

Have you tried the free/demo version of EZNEC? "How To Use" that
antenna modeling program is well described in in HAM publications by guys
like Cebik http://www.cebik.com/amod/amod103.html. It is easy to
use even without outside assistance. I'd like to know why every ham with
antenna interest doesnt have a copy of EZNEC. Try the moseling
software at http://www.eznec.com/ then, if you have time, tell me
why it isnt of interest to you.

You mentioned insensetivity above, are there any other polarities
insensitive to others ? I note that weather antennas are now migrating
to
dual diversity antennas for horizontal and vertical, is it possible to
totally isolate those too.?

Hi Art

I may make mistakes by using non scientific terms. When I read my post,
I realize that nothing is actually defined by my above statement. I would
submit that a LHCP antenna will receive no RHCP signal. I'm sure you know
that any linearly polarized antenna is insensitive to linearly polarized
signals that are orthogonal to the line of polarity of that antenna.

Tell me more about the "weather antennas". What frequency do they use?
Where do they transmit from?

Jerry

Weather experts have found that using both horizontal and vertical
polarizations coming from the same antenna tho in separate pulses that
with oncomming clouds and weather systems that the received picture is
more defined where size of droplets can be determined as well as other
things.
I would suggest that things like wind shear would also be more
discernable.
My antennas because elements are non defined in placement to each
other are capable of multi polarizations which is why I posed the
question.

I would buy only programs that allow for variables in dimensions such
that the program can migrate towards more advantageous models. I
really see no advantage purchasing a program that solely determines
the merits of a model
that you alone have put together. The variable dimension forms tho
more expensive than the standard forms are now comming down in price
tho one in South Africa is still in the four figure range for
unlimited pulses and variable dimensions but there are some that are a
lot less expensive as more algorithms come to the fore.

If you put that same question to Google it would be more informative.
Apparently every forward thinking nations have scientists dabbling
with it
funded by the concern with global warming. I find this all very
interesting because as a ham I had been concentrating on vertical and
horizontal polarizations only Seems like space has opened up the
antenna field such that many will be able to review the path that
antennas have taken over the last century that have appeared to stymy
progress and with an open mind
change course

Lots of questions, lots of possible answers.. here goes:
1) While a theoretical antenna of one polarization sense is
insensitive to the opposite sense, in reality, antennas are perfect,
particularly "off boresight". that's what axial ratio tells you.. how
"perfect" is the CP (1 is perfect, 0 is a linear pol, non circular
antenna). Think of it as a continuum from a straight line (linear) to
a circle. Elliptical pol is the general case, and axial ratio is the
ratio between the major and minor axes of the ellipse (to fully
specify the antenna, you'd also need to specify the angle of one of
the axes and the "handed ness")

2) The radiation from an antenna, in a particular direction, can be represented by a linear combination of two orthogonal polarizations (orthogonal here has a special meaning... two linear pols separated by 90 degrees is but one case). The two popular systems are CP and linear (that is you say that the field is (a+bj) horizontal + (c+dj) vertical. You can do the same for RHCP and LHCP. (and, actually, for any two linear pols that are different). This is one way to "make" a cp antenna (combine two linear antennas with the right relative amplitudes and phases).

3) bear in mind that an antenna may be perfectly CP on boresight (axial ratio=1) and not CP in other directions. In fact, it can be proved that no antenna can have the same polarization everywhere (see the "hairy ball theorem")

Much more info can be found on the web.. wikipedia has an entry on polarization,antenna books talk about it (Orfanidis' book is online at Rutgers) Kraus has a nice discussion (particularly appropriate since axial mode helical antennas are particularly good at being CP)

Now to weather radar...
spherical particles (raindrops) are perfect "depolarizers"... send any pol to the droplet, and what comes back is equally distributed between both pols. (spheres are used as cal targets for this reason)
ice crystals, on the other hand, show significant polarization effects.
Since the polarization effects are also "size of particle" dependent (relative to wavelength) you can also figure out things like particle size distribution. that way you can tell the difference between a few big raindrops and lots of little raindrops.

Most other physical phenomena show some polarization effects, which is heavily used in radar remote sensing.
You transmit radar pulses of two different polarizations, and receive the returns with a dual pol receiver, so you essentially get 4 different complex numbers (HH, HV, VV, VH, for linear pol) for the backscatter.
An example might be looking at forests.. in the summer, when they have their leaves on, they pretty much randomize the polarization, but in the winter, the Hpol backscatter is very different from the Vpol backscatter. Plowed soil has a very different polarization signature from flat earth. Conifers look different from broadleaf plants.

Hi Art

Sorry Art, my news server seems to have garbeled up your last post. It was completely scrambled so as to be unreadable. Could you please tell me what frequency the "weather experts" are using when they use polarization divirsity? About 90 percent of my antenna learning is directed to learning about weather data reception from NOAA satellites. Anything I can learn from the really smart guys like you will be greatly appreciated. Please tell me more about radio frequency related weather signals, and how polarization diversity is used.

Jerry

I'm partial to 4nec2 (which is free) which uses the standard NEC2
engine underneath. It has variables and optimizers as well. It can
also fire up the NEC4 engine, if you have a copy of it.

While I wouldn't insist that hams use EZNEC, I do think that if you're
interested in antenna design, SOME modeling program is worth fooling
with. Original vanilla NEC is a bit archaic in it's interface
(punched cards and line printer output) but there's lots of front and
back ends (e.g. EZNEC, 4nec2, MultiNEC (from AC6LA), SuperNEC, etc.)
Some are free, some cost a little, some cost a lot. If you wind up
having to model BIG things (thousands of segments, dielectric media,
etc), then the pricier products are easier and faster. Most hams are
modeling things that are well represented by wires, so all the Method
of Moment (MoM) codes, of which NEC is an example, work pretty well.

Any cross polarization situation will exhibit insensitivity to others.
For instance take a vertical antenna and a horizontal antenna at a
distance. There is a signifant reduction in signal strength.
Or take a dipole oriented NS and a dipole oriented EW and you will see a
loss of signal also.

1414. HF random wire antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2007-02-14 19:38:00 UTC
From: Juha Ojaniemi <Juha.Ojaniemi@iki.fi>
Message-ID: <53h6ouF1stvq2U1@mid.individual.net>
Source record: 45828

Hi,

I have limited space for a HF antenna, so I built a random wire antenna.

The instructions I found (in Finnish):
http://koti.mbnet.fi/takamaa/tiedostot/Satunnaisen%20langan%20baluuni.JPG

I wound the balun and bought 20 m wire. Then, OH1NT, an older ham, adviced me that 40 m wire would be better for 80 m band. So I hung up 40 meters of wire.

So far I have received good reports at least from European stations. I look forward to DX QSO's.

Here's my blog entries on the subject (sorry, in Finnish):

David , maybe it was I that was not so clear.
My arials are based around a cluster of elements that are at various placement with respect to each other tho all are resonant as is the cluster as a whole. So when it is used for diversity operation because more than one element is resonant choices can be made as to where to feed to advantage
as quick as possible with a change over such that the reflection is meaningful with respect to time. I don't believe that the weather people radiate both at the same time as the search is for purity with respect to polarity. In fact all the arials ive seen cannot possibly be pure since they all seem to have elements in the vertical position which cannot lead to purity in any form. I saw one in a antenna book (shelnikov)where the elements were in helical form one behind the other at a 90 degree offset but I have no further knoweledge of that one. Somebody mentioned that some radios are now made with two ports such that the receive portion automatically switches to the loudest signal to overcome fading so I may well be incorrect about simultaneous transmissions or even if two arials are in use.

Very true, a yagi is a planar antenna i.e on a single plane whereas
only one element is resonant and where ALL others are parasitic. This
also holds true for a log periodic except the frequency is a variable
which selects the element closest to resonance for the theoretical
feed point i.e. of matching impedance to the feed point impedance. The
point about just one element that is resonant is the reason in my mind
that antenna advancement
has been retarded over the last hundred years excabated by the design
of the yagi which is really an empirical design that denies the
simplicity of normal radiation and its corresponding mathematics. Now
I know somebody will immediately jump to the dual driven element forms
but that is beside the point under discussion.

> Andy W4OAH

Quick answer you say ? A change in direction of current flow inpedes
that flow. Radiation is at right angles to the radiator thus radiation
drops of at the centre at that same point.
Short enough ?

Tam,

Thanks for the information and the URL on Lewallen'w work. This
configuration appears the same as the front end of the channel master 3018
VHF/UHF combo. As such it appears I could expect 10 dBi to 8dBd from it. I
will try to run down the analysis source and see if a dipole feed impedance
was computed. Thanks again.

1423. Re: Need Ideas for HF Antenna at Fire Station

Newsgroup: rec.radio.amateur.antenna
Date: 2007-02-14 23:46:02 UTC
From: ml <m@di.net>
Message-ID: <m-ADEF89.18460214022007@news.verizon.net>
Source record: 45837

2 ideas poped into my my head

you could get a verticle antenna , burry the ground radials or hid them
and use some sort of tilt mount like dx engineering has, perhaps if the
building has say in the back a long side to it it can be mounted
horizontal when not in use then fliped up when needed

a variation of this might be a collapseable tower or mast if the
roof is flat and the antenna lowered is near the roof it should be
hard to see

another idea might be to use a tuner like a sgc237 at the center or near
center of a dipole

a properly sized dipole would be somwhat visible thou i think the most
hard to see off all antennas, you could mount the sgc on the lower part
of a center supporting mast run ladder line to the dipole center up
along a plastic/fiberglass support of course it would certainly tune
more efficiently than a at the rig tuner

but it's just my crazy ideas

Tony
Nottingham
England

14 February 2007

TO: All People Who Care

I am a private individual posting this message to help Laboratory Animals. I apologize if this message is out of place in this group but I think you need to know this.

A new European Chemical Testing Policy called REACH has now been finalised by the European Union. Under these proposals Chemicals of every kind - from those used in industrial processes to the ingredients of consumer products - will be tested on Millions of animals from mice to fish to dogs, causing untold suffering.

If you believe that REACH should make more use of Alternative Testing to test its Chemicals then please take action now.

If you are a European citizen please contact your local papers and own MEP asking them to promote the development of humane non-animal testing methods under the REACH legislation, which is the best hope we have for sparing animals the misery of a testing laboratory.

A sample letter can be found at the BUAV (British Union for the Abolition of Vivisection) website at www.BUAV.org (Select Campaigns, Chemical Testing, Get Active then Writing to the local press).

For all Non-European members, you can still help. Please tell all your colleagues and friends in the UK and Europe about REACH.

Everyone can help and you can make a difference.

Thank You

Art;

OnPage 23.35 of the ARRL 2006 Handbook is a Graph showing the relative
loss between two antenna's for various angles from 0 degree to 90 degree

misalignment. For 0 degree misalignment there is no loss, at 50 degrees there is a 3.84 dB loss and at 80 degrees there is a loss of 15.2 dB. 90 degree misalignment shows an infinate loss. This is for linear antenna's. Circular Polarized antennas of opposite turns show an infinate loss between two antenna's.

Art;

I responded to your other email but what you are saying here is that you are using multiple antenna's which are selected automatically to sense the strongest signal reguardless of the orientation of the received signal. i.e. if the signal is at 45 degrees the antenna that is fixed to a 45 degree angle will be the strongest signal. If I have it correct it makes perfect sense but is not cross or circular polarization just rotated wave front.

Wikipedia gives a definition of delay line; a length of transmission line is technically a delay line, but often for longer delays, a special line is made in which the center conductor is a wire wound around a core (often of the same material as the dielectric between center and outer). The winding should be done with space between the turns, not close-wound, to give more uniform delay versus frequency. For a uniform TEM transmission line, the delay time is the square root of the total capacitance between the conductors times the total net inductance of the length of the conductors: Tau=sqrt(L*C). Many E&M texts go into how to accurately calculate the inductance and capacitance for coaxial line with straight conductors.

In an antenna, you can increase the inductance by adding a lumped inductance, commonly called a loading coil, or you can replace the straight wire with a wire formed into a helix. Google "slinky antenna". You'll find lots of info. I'm not making any claims that a slinky antenna is either a good antenna or a poor one; it's just one way to make a shortened dipole or monopole antenna, or even a shortened Yagi.

Cheers,
Tom

In the early days of computers they used to use a length of wire as temporary memory. At the start of a store cycle a piece of data would be input to the wire, after a period of time the data would come out and be placed into the computation.
Admiral Grace Hopper used to give an example of time and delay in her speeches. She would say that one day she called down to the computer department and asked for a micro second. They sent her 1000 feet of wire. She then called down and asked for a nanosecond, they sent her one foot of wire. No point to this just a good story.

Yes. I wasted *hours* at Field Day a few years ago trying to make FM
contacts on 440 with my beam oriented parallel to the horizon. (I play with
TV DX and I brain-cramped with my 440 beam.)

When somebody pointed out my error, I wanted to crawl in a hole. This
monumental screwup came despite the fact that I had been making 2m contacts
with a correctly-oriented beam. Go figure. But it proved the heck out of
the theory!!!!

(I am working in GHz range and so the spacing of multiples of
wavelength means it will be only few cms.)
One more observation i have made is that i have placed my antennas on
a rectangular plate and then on a curved surface. The former setup
gives me around -20db gain at 270deg, i.e back side of the rectangular
plate whereas in the latter case there is no such diffraction effect.
Why is it so?

Most would stay with the un moderated group. History has shown that.

I have used moderated news groups and found in general they are a
waste of time. They end up reflecting the moderators view points and
opposition is stifled. So I avoid them. I see this is cross posted to
a moderated group to which I do not belong.

>be missing much, but there ya go... I deal with the hecklers,
>goofballs, and
>wanna be porn stars by not reading their posts. Fairly simple really.

Which is the self governing mechanism of most news groups.

I see the proposed rec.radio.amateur.moderated as a waste of time and resources of those who handle such matters. So I would say that in the long run we would be better off with one un moderated group than an un moderated group along with a moderated one which dilutes the pool. Just kill file the posters and threads you don't want to read and let life go on a lot simpler with more people exposed to the knowledge that would otherwise be diluted by spreading it into another group.

Me? I would not bother subscribing to a moderated group.

My needs are for amateur antennas, wires, verticals, yagis & etc.
Just want to model antennas which I have ideas about or those which are
already built and what might happen if it were modified to another
configuration.

I guess if price were a consideration no more than $150.

I have looked at EZNEC but there are others out there also. This is why
the question is being asked.

Which ones do you like and why? What one would you recommend to me and why?
What features do you like about the program you are using.

Basically, you be the sales person for whatever modeling progam you use.

I suppose any good modeling program would work for amateur antennas.
What I would appreciate is a good as to which one you like and why.
Recommend the one you like best to me. I am willing to spend up to $150
for good modeling software. Easy to understand and use would be important.

Its my understanding that the author of EZNEC hangs out in this group, I
wish he would put his 2 cents in also.

David I am not privy to a copy of what you are talking about but we may be talking at cross purposes. My point is that a element at right angles or parallel to the earths surface cannot present a pure polarised field.
When looking at a radiating beam you have two vectors, one at right angles to the other, therefore I fail to see how radiation would appear at right angles to the earths surface. True the right angled vector is reduced when it is broken up into two vectors when it is seen as curl but the horizontal vector cannot be removed or cancelled unless the element is tilted somewhat.
Anybody can prove this to themselves by the use of the plethora of computor programs Admittedly the tilt required is small but it is there none the less.
Art

Art;

Your right horizontal is horizontal and vertical is vertical and never
the twain shall meet.

Must admit that I don't often get involved in moderated groups either.
news.groups.moderated has had more posts from me than any other, and I've
only posted there twice.

Couldn't say for certain, but some news clients will filter out
crosspostings on download. The one I use, for example, does it.

FWIW, I have found moderated groups to be not very useful unless they are for a very narrowly defined topic. I avoid them when possible.

Is there a way to have a newsgroup server reject all cross-posted messages? The cross posting to multiple news groups seems to be the source of much of the garbage. I suspect the whole newsgroup concept would be improved if cross posting were automatically eliminated. (I notice this message is being cross posted !)

Call To Arms, means, you will inspect your weaponry and prepare to do battle. Duty Stations, means, all men and women must assume their duty stations, weapons at the ready. Fire When Ready, means, man or woman your weapons, sight the target, finger the trigger, and fire when ready. Cease Fire Procola, means, continue fireing until the enemy targets are dispatched, and there is no sight of an enemy anywhere on the horizon. Procolas means, after ending all possiblities of any lingering survivors staying alive. It means to wipe them out, and leave no survivors.

This means, it is time to kill all Lesbianists, and all other enemies in my universe, the many groups of naughty kids in my universe, rascaleers and others, and we will continue this fight, untill they are all dead, and in my Epcot Centers, or untill they have surrendered. Rascaleers are evil people who wish only to harm others.

Updated: 18-01-07 Rev.a.00.a 02:50 PST

Religious Practices

This is a little confusing, but hold on, and I'll try to explain it. There are many parts to my religion. We call them, parts, but we can also call them, practices, some of them, but not all of them.

We have the fundamental 'root' practice, which is sexaling. From the root practice, comes all other practices.

There are side practices, and there are derived practices. There are also, accompanying practices. There are many other types of practices, but I don't remember the names for them all, right now, as I'm still

amnesiatic, and will be for a long time.

Fistiker Practice

Bringing about orgasming in another person is a fistiker practice. A fistiker practice is a side practice, but it is also something a little different from a side practice, depending on how you bring the orgasming about, and depending on how many people are involved, and depending on who is the primary person, the person whom we are working on, and who are the helping people, the people who are joined together, to help the primary person to orgasm. There are a number of other dependencies as well.

What Is A Dependency?

A dependency is some thing that is needed that will help to define something else.

As in the case of an accident victim, we have a crutch to define one level of severity of an accident victim's situation. But we might also have a wheel chair to define another level of severity for the same, or other, accident victim. These objects help to determine how badly or miserably a person is injured.

A crutch can help define a level of severity in the injury. A wheel chair can help also to define a higher level of severity. These are both dependencies. They help us to define something, and they are used to help us to define an accident victim's level of severe injuries.

When Sexaling

You can use your lips, for example, or your tounge to twiddle the toes of a woman, and the woman begins to orgasm. That twiddleing of your tounge on her toes to help her to erotem, and to experience erotistical orgasming, can be any number of things, depending on the involvement and complexities of dependencies.

Rubbing the vaginal face, the vaginal wall, or rubbing to either side of the vaginal crevice, the labial folds or felates, can help a woman to erotem and erotistically orgasm, and depending on the involvement and complexities of dependencies, the dependencies can be any number of things, if we try to define the sexaling activity more fully and completely.

We'll skip this for now, as it is a little too difficult to remember, right now. Just remember, the primary practice is sexaling, and that sexaling is like the roots of a tree. All other religious practices grow out of the 'roots' of the tree, sexaling, and can be defined in many different ways, such as a helping practice, a side practice, a subsidiary practice, a canceling out practice, an accompanying practice, and there are many many other terms for what kind of practice some thing is, depending on what dependencies are involved.

Labia And Felate

What is the difference between a felate and a labia?

A felate is the skin tissue of the outer surface, and some of the tissue of the tips and edges of the labia. It does not include the inner side of the labia, but only the outer side, and the surrounding edges, as far as I can remember.

A verb, or action word, as I call it, is 'felate' as in 'Felate that woman's or girls' left felate'. That means to suckle on the left felate of the woman or girl.

Felate is a verb, but it is also a 'nominal' word, or naming word for objectifying an object.

Do we say 'Labialize that woman's felate!' To labialize something is to make something into a labia. We wouldn't, unless we were a doctor, say that about a felate. But we might say it if we were doctors, and we had a woman who met with a bear, and the bare clawed at her genitals, and the sharp claws ripped her labial skin up, then we might say in a surgeon's room 'Labialize that woman's ripped up labia.' That would mean to stitch it up, and make it nice and neat, and clean and well stitched up, and then useful to her, again, and it would involve a lot of surgery, as many nerves would need to be connected, as they had been ripped apart, and the wiring was all dislocated. But in the end, we would be able to fix her labia, and her genitals, if they were also hurt, and then we could dismiss the patient from the hospital, after the labia healed, and after she recovered from her trauma of having her labia shredded by an impolite, rude, mean, uncaring, and hungry bear.

Genitals, Titties, The Labia, And The Many Sexaling Organs

The labia is not the genitals, but some people do consider them as a part of the genitals. The genitals are inside the woman's vagina, in my way of thinking. The vaginal wall is not part of the genitals. The vaginal orifice is part of the genitals of a woman. This seems odd, doesn't it. Well, that is how it works, in my brain, and I designed women, as well as men. If you notice, in my writings, I've talked about the draft table, and the throttle. These are major parts of a woman's genitals. They are inside the vagina, and you can reach them through the vaginal orifice. Before you get inside of the vaginal orifice, there are a few things outside, such as a pee tube, and an ejaculate tube, and the clitoris, as well as the labia. These are not part of the genitals, but are working parts of her sexaling organs. A woman's or girls' sexaling organs are not equal to her genitals. Genitals are for baby making, and for other purposes. Titties are not part of the genitals, but they are part of the womans' sexaling organs. This will require a long discussion to clear up, so I will save it for another day.

Bears In The Woods

That's the way it happens some times, when women or girls go out into the woods, and sexal with their female friends. They can get hurt by

bears, if they are not accompanied by men, who are tough, and strong, and who stay alert, to guard and watch out for dangerous animals, such as bears, wolves, cayotes, bobcats, puma, and even racoons. Racoons do attack humans, if they smell some thing that will taste good to the racoon. If a person has a skin tear, and is bleeding, even a tiny bit, the racoon will smell it, and come running, and then find the person, and so will panthers, and all kinds of animals will come, and it's just like a bunch of sharks and fishes of different kinds, and Moray Eels, they like the smell of blood, and they come and investigate, when they smell it.

Women and girls have periods, and it is not every twenty eight days, as I've explained about before, and blood runs down, out of their vagina, and they generally do not know it, as it is only a tiny drop of blood, or less, most of the time, and the blood is often wiped from the skin surface, when the woman or girl is on the potty, or toilet, and the woman or girl will not even see the tiny drop of blood that comes out of the vagina and drips down the labia, on the inside, and then falls or dribbles down to the felates, and then falls off the felates, while she is on the toilet into the toilet, or while she is out doors, and walking about, onto the earth, if the woman is walking on a park walkway, or bicycle path. If she is wearing underwear, it will not fall onto the earth, but it will dry up on the panties, or underwear, and the smell of the dried blood will attract wild animals if she is out doors, walking or jogging in a wooded or regional or rural area, where there are lots of, or even just a few, animals.

Pumas can smell the blood, from miles away, and so can tiny oselots, and bears, and many animals can. They can smell blood, because they know they need meat to survive. That is built into their brains, that are located throughout their bodies, and not only in the skull, and animals are very sensitive to the smell of blood, as well as to the smell of urine, and to the smell of poop. Some animals, such as racoons, will come up from behind a woman, and grasp at her panties, as the racoon may smell the odors of fecal matter, from her butthole. Men may be raked by the claws of raccoons from behind, as they smell the odors of fecal matter, and try to find out more about it, as the racoons know that there is something delicious hiding behind those odors from the buttholes of women, girls, men, and boys.

Expecate

When women and girls go out hiking, it is best to wash out the vagina, first, and then use a fermented oil, as a douching agent. The oil will help to slow the flow of the blood down the inner walls of the vagina, and it may help to trap the blood, and make it difficult for it to leak out, unless the amount of the flow of blood, is very large. In that case, it is best to stay home, and not go out, when a large amount of blood is expecated from the vagina. Expecated means to expell outwardsly. Expectate can also be used, as it is generally the same word, that is, and it also has generally the same meaning, but

perhaps it has a few more uses, maybe, but it is from a variant language of the English language, and is basically the same word.

You should expecate your fluids in your vagina, from your vagina, before you go out hiking. If you know when your period is, and there are ways to tell when you have a period, or when you know when you are about to have a period, than if you normally have a large amount of blood flow from your vagina, as that has been your experience, it is probably best to go and sunbath at the beach, far away from wild animals and their habitats, or by the pool side. Racoons sometimes come out of the woods, to the shores of beaches, and trumbel along, listening and watching, and sniffing the air, when they smell dried blood, or wet or moiste blood, inside of the swim suit lining in the groinal area.

How Do You Tell When Your Period Is?

To learn when your period is, you need to look into the toilet bowl that you pee into, and then see if there is any red droplets. You can place a piece of toilet paper onto the surface of the water, and it might help to show the redish color mixing with the urine.

Another way is to take a piece of toilet tissue paper, and wipe your felates, in the morning, or during the day, or at night. Night is a good time, but during the day, it is just as good. Some women like night time because they feel the day is finished, and they are now going to make a final check. Well, it doesn't always happen the way we want things to happen. You might start leaking blood fluids, at two or three or four or five, a.m., or at six, or seven, or eight, or while you are in the shower, or in the bath tub, bathing, before you plan to go out for the day.

It may take you several years for you to find out when your period begins, and when it ends, by checking for blood flow. When you have determined the number of days between one period and the next, and you are absolutely certain of it, and you have confirmed it, many times, and you have checked to see if there might be something you didn't notice, at other times, when you checked, eventually, you'll learn when your blood flow begins, and how long it lasts, and when the next blood flow begins. Once you know, then you can time your excursions to the woods, or to the beach, with your friends, both women and men.

Bears, Wild Animals, And People

Men are needed to help scare bears away, if they come to close, and pepper spray is a good way to get them to leave the area. Bears do not like the small of pepper spray, and you need a cannister of pepper spray that will fire fifty to eighty to one hundred and eighty five feet or more, to scare away a bear, safely.

Loud noises surprise bears, but hungry bears get angry and feel challenged by you, and may come at you at a fast pace, and not stop, once they are angered. If you are a good shot with a rifle, and you

see a bear, from a few hundred feet away, and it is moving slowly, towards you, following you, you can shoot it with a good fifty calibur weapon, from that distance, and it will go down, in an instant, if you hit it square in the noggin, about one inch or less above the nose.

You need to be a good shot, and several people should aim, and fire at the same time, to kill the bear, to be sure some one hits it, and then puts it down, and kills it.

Do not think that because you have one rifle, or two handguns, and a rifle, that you are safe. If you do not know how to shoot, and if you are an inexperienced marks woman, or marks man, than your chances of hitting the bear are near zero, for all three of you, at three hundred feed.

You need years of practice to become a good marksmen, and you can start with the lower calbur weapons, to get a feel for weapons that fire projectiles, and that make loud noises.

There is no such thing as a friendly bear, and people think, 'Oh, look! Isn't she cute, that bear.' If they think that way, they might as well have left their last will and testament behind, and signed all their assets over to another person.

Bears are animals that need to eat just as humans do, and just as all animals do. If you are so foolish to think that bears are cute, you are a lame brained idiot. Bears are dangerous animals. And so are all wild animals. If you think a racoon is a cute animal, you get the lame brained award for the year award, and trophy to sit on your desk at home to remind you of how stupid you are.

Brad Pitt, And Angelina Joline

Only idiots would think that wild animals, that eat people, are cute. They need remedial training, as they do not understand that their lives are in danger, every time they walk out the door of their home. Even in the cities, there are nasty people, who smile, and pretend they are your friends, and these same people, such as Hillary Clinton, Brad Pitt, Cheryl Davis, a friend of Brad's, but that's his current girl friend, Angelina Jo-line. She is not a Lesbianist, and Brad pretends to be her friend. He likes to watch her get eaten by bears, my abominant kids, when the Lesbianists feed humans, one at a time, to the bears, or to the crocodile abominant children of mine.

Abominant Elephant Kids

I have carniovorus, human being abominant elephant kids, and they are rude, mean, nasty, and really terrible. They scare people, and then they pick them up with their trunk, and place them on their head, and then they tell them not to move, or they will stample on them, or tromp downwards, and crunch them, painfully, from the foot, to the shin, to the thigh, to the pelvis, to the waiste, to the lower tummy, to the mid section, to the chest, and then the neck, and then the

head, finally killing them. They will take a person, pull the person up and lift him or her up into the air with his or her trunk, and then pull the person into his or her mouth, and then crumple up the person, and then spit the person out, and the person is all broken up, and chewed up, with all the bones, broken, in the legs, and in the arms, and in the waiste, pelvis, torso, neck and shoulders, and head.

The Lesbianists use lots of these elephants. They are pretty to look at, but they are mean, and nasty. When strangers see them, they think, 'Oh, what a pretty elephant.' They don't know that the elephant is my abominant kid, and can speak English, as many people recently found out near Africa, in Sri Lanka, and then also in New Guinea.

They were very surprised at the talking elephant. But they didn't know that the Lesbianists had let the Elephant, my abominant kid, lose from the cages that they kept him sealed up in. There were one or two, or maybe eight of them, in Sri Lanka, and eight or nine in New Guinea. Lots of people got eaten up, and killed. The elephants are still lose in New Guinea, but in Sri Lanka, they herded them into the pens, and brought them to New Delhi, to then begin a rampage in New Delhi.

Well, the Lesbianists are doing this, daily, because they feel they have lost this battle, and that they are just wasting time, doing nothing, as they can not get to me. So they want to have a lot of fun. Now they are releasing lots of my abominant kids, in many places, and in New Delhi, Bombay, Sri Lanka, and New Guinea, many people have been hurt and killed by these idiot kids, these abominant elephant kids of mine. The Lesbianists have thousands of animals they want to release, out into the public, in England, in Switzerland, Georgia, South Carolina, Paris, and many other places.

The Lesbianists think they are going to have a lot of laughs watching the abomniant kids of mine, tear people up, and rip them to shreds. They also think that the animals, who are not abominant kids, but are just bizarre animals, that catch people in very large, nets, that have threads as thick as ropes, and that are very sticky, are going to do a lot of wierd and crazy things, no one here on this planet, other than them, have seen. They think they are going to get a lot of laughs when they see the mayhem and havoc, the disruption to society, and frustration on the faces of people who get caught in the nets, and then turned into living mummies sealed up in a type of pulpyish paper so the person can slowly disolve, but stay alive, for up to a year or more. Maybe as long as ten to thirty years, in some cases, and I'm not kidding.

You may think I'm kidding, but I'm not. This began a few days ago, and the Lesbianists are intent on continuing this, for the next few years. Isn't that surprising. I never expected that. They are very strange people, aren't they. They are real sicko's aren't they.

I think you should all go and meet my kids, with a day pass, and ask them about it. Other wise, you might find your self in a very large

spider's web.

Labiating A Labia

To labiate is to suckle the labia, and to take one or the other of the labia into the mouth, and tickle it with the tounge, or twist it gently with the lips.

'Labiate that woman's left labia!' 'Felate that womans left felate!' The difference is, labiating is to suckle the entire left labia, inside or under the edge of it, on the inner side, and the edge of it, and the outside of it.

Felateing the felate, is to suckle the edge of the labia, the upper exposed edge. It does not include the labia, in its entirety. Only the upper, protruding skywards, or in which ever direction it is pointing, that portion of it that is extending outwards. If you lift it up between your finger tips, you'll pull up on the entire structure revealing the underside, or the unexposed underside of the labia. There is also the outer side of the labia.

The Felate is the top tip edge of the labia, generally speaking, and it is itself an isolated system, and not part of the labia. It's connected to the labia, but it serves a different function. It droops downwards, to seal out the possiblity of any thing entering the vagina from below, in an upwards moving manner. Bugs can not fly up into the vagina, as the felates prevent them from flying up into it. Without the felates, the vagina would be unprotected. The labia would not protect the vagina, as the labia is merely the skin tissue mass that the felates are attached to, and in an instance of removing a felate from a cadaver, or dead body of a woman, or girl, once the felate is removed, the labia have no closure over the vagina, in most women and girls.

There are exceptions, as we've had many animals in our heritage line. There are many differences when we line up ten women, and inspect their vagina, their felates, and labia, their bumbey pack, as children are encouraged to call the lower hanging sexual organ of the vaginal cape, as it is also called by doctors.

On this planet, the bumbey pack may not be called a vaginal cape, with the inferior texts with unadvanced, primitive, witch doctor level sexual sciences that do not help any one along, such we find with the myth that women and girls have a period every twenty eight days.

That is total nonsense, as I've explained about it, before. The truth is, every few days, to every eight to fifteen days, to even eighteen days, or evern thirty two or fifty five days, depending on where the woman has grown up and where her ancestors have grown up, the number of days between one period and another period can be very dissimilar, from one woman to another woman. Some women have a period every two or three days, or even every day. There is no reason an ovary can not fall, every day, several times a day.

An ovary is so small, no one can see it, without special optical technologies, such as pass through see through technologies, and other optics, and other videoing technologies. A microscope is an out moded, ancient, and novel device, fit for only museum use on display shelfs. It's like an old car of the twenties, or there abouts, or even earlier, of course, depending on how sophisticated it gets. Micron microscopes, the so called, 'electron' microscopes, are a misnomer to begin with, as an 'electron' is not a fictious concept, but no one knows what an electron is, generally speaking except for the Lesbinists.

An electron is a small bit of electrically heated plasma, that you can heat, with the right technologies. It can fit on the tip of a pencil or pen. This is a big joke to the Lesbianists, as are also their jokes about protons, and neutrons, and nuclei, or the so called combined nucleus, as in 'nuclear' family. Nuclear family, is not a 'tight' organization of two persons, and their children.

A nuclear family is a family that has been nuclearized, that is, exposed to radiological salts kiddies, and their radiative or radiological energies. That's another one of the Lesbianists' jokes on all of the scientists who the Lesbianists could get to swallow it.

What Causes A So-Called "Nuclear' Explosion Or Detonation?

A vast number of children are making babies at a very high rate of speed, and the energies that they give off, as they make babies, and then peel off from the area where they made their babies, one after another, as they rocket away, is what causes a nuclear blast. The tummy mommies and tummy daddies are making babies at such a frantic pace, they make millions and billions, and trillions, and more, before you can even send a signal to your eye lid to blink, from your brain part that sends the signal out. The signal will travel just a very short distance across a crupture, not even half way, more like, one or two feet in distance, if we are to look at the size of a crupture as the same size as our current universe. It travels about not even one foot, not even one inch, and not even one millimeter, and not even one millionth of a millimeter, and far smaller than that still, before the parents are already through making babies, and they have retired, and passed on, and several kabillion generations of families, and multiply that by a very large number, and you'll get how many generations of families lived and died, and passed on their DNA to their sons and daughters.

It's a hail storm of erupting magnitude when the tummy mommies and tummy daddies begin making babies, and making their families larger.

It all happens so rapidly, with more than that number of successive generations of families, in less time than the energy pulse will travel down an optic nerve, across a crupture, that very minute or very tiny distance, as I stated above.

That kind of frenetic baby making activity, makes for a lot of heat, as well as, it generates a lot of stresses, and a lot of energies go flying off in all directions, as the sexaling couples experience many nice orgasms and eroticisims, together.

Temperatures, their body temperatures, collectively, and the incredibly vast number of movements, which also generate temperatures, by the animals, the tummy mommies, tummy daddies, tummy babies, the relatives, and the many generations of families, go skyrocketing, and the magnitude of numbers, and the intensity of all the activities the animals are busy with, as they make tummy babies, simultaneously, or nearly simultaneously, is of phenomenal proportions.

If we slow them down, to our pace, and then compare them to our pace of life, they would be just like us, and things would move slowly for them, and not much would change, for many kazillions plus years, and then many, many more years.

However, they are moving so much faster than we are, and the length of time they live, to them, it is a long time, four or five, or eight or nine hundred years, in our time, maybe, in some cases, depending on the type of radiological salts kiddies making babies.

On their scale or pace of life, they live that long. But on our scale, the length of time they live, is so tiny, we can not measure it, unless we have a very high level of advanced mathmatics that can account for such a small time period, or span of life.

Anyway, the frenetic adventures of the colony of radiological animals, when they start to make babies, after they are woken up, and prompted to make babies, with a detonating surge of heat energies, light wave energies, pressures energies, trampolining energies, which get them started, with the right combination, of heat, light, atmospheric temperatures, atmospheric pressures, food sources avaiability, drinking water avaiablity, trampolining energies, and a number of other types of energies, that awaken them, and then get them turned on, and sexaly active, they will suddenly erupt into a frenetic, mass of baby making furor, to us, any way, and with that, we have our so called, 'nuclear' detonation.

Cleansing Your Self With Your 'Built-In' And 'Attached', Cleansing And Washing, Clearifying And Erasing Energies Producing Genitals And Sexaling Systems, Eroteming And Orgasming Nervous Systems, And Baby Making Related Purifying Energies Generation Stations Aparati, Or Apparatuses, And Armatures

You women and girls, your vagina is your Holy instrument for assisting you to cleanse your self, and wash away the dirt and grime of daily living, the insults to you from strangers, the verbal abuse you experience in your arguments and conversations with friends and family, neighbors, relatives, work associates, and community acquaintances.

Your Holy body is a weapon to fight back against all the negativities you experience in your life, as you orgasm and erotem, showering off purifying energies, and lots of other beautiful other things and dings, as you vibrate your entire body concordially, in harmonic rythym, cadence, and rapture, with my Holy Body.

Your breasts, your butty butt, your butty butt hole, your vaginal hole, your groin, your throes, your vaginal cleavage or labial folds as they are called here by these nitwittish doctors on this planet, who do not know any thing about the human body, your chest, your back, your legs, your arms, your hands and fingers, your ankles, feet, and toes, your ears, lips, mouth, tounge, cheek, your rectal cavity, your tummy button, your stomach, throat, your brains, and you have many more than just one in your body, but many millions and more of them in your body, and that is not an overstatement, and every part of your body, inside and out, your many nervous systems and all your organs, they are all set to orgasm and erotem, and generate purifying energies with the help of the power company, as I've explained about them, before.

Ticklement Tuning Forks

You have ticklements, tuners, or pitch fork tuning forks, that chime, in every cubic millimeter to every cubic inch, and in even tinier places, you have tinier ticklements, or tuning forks, and in larger areas, you have larger ticklements, or tuning forks, and they are all set to vibrate in various patterns of sexual thrilling eroticisms, and orgasming ecstacies, as you pump up the levels of sexalating energies you have available to you, in you, and showering off from you, and those patterns and focal points change, slightly, minutely, as every micro second goes by, as we change our location in our universe, and our relative location or position to every thing else in our universe changes, from night to day, and from day to night, ongoingly, non-stopingly, never repeating the same set of tuning focal patterns. Focal patterns are frequencies.

Focal Patterns

These frequencies, or harmonic consistencies, are harmonic displays or the 'in rythm' with GOD, consistencies that allow you to be united with GOD, me, my devine and holy body, and my devine and holy mind, and being or GOD SELF and GOD BEING, every moment.

Men and boys have the same ticklements, or tuning forks, and they are located in every organ of their bodies, just as they are in women's bodies and in girls' bodies, and they allow all of you children of mine to stay in frequency with me, as you sexalate, erotem, and orgasm, practicing my religion, and as you live your daily lives.

These many ticklements and tuning forks are all connected to your brains and to your nervous systems, and each living being in your body, has them as well, and every living being has them as well.

All my children, animals, living beings, and human beings, are all connected to me, through these tuning forks, and also, through the holy bodies all my children have inside of them, and also through a myriad of other mechanisms that I have functioning in your bodies, in your astral 'energy' bodies, and the many millions of energies bodies each of you have in you. My animals children and living beings childrens have fewer connectivities and fewer energies bodies, as they do not need as many as my human being daughters and sons. This is because you, my human being children, need to be more connected to me, as you are the only ones who can actively practice my religion, with your own self determination, and desire to practice, to become closer to me, GOD, purer, and holyer.

I'm connected to all of you, day and night, three hundred sixty five days a year, in countless many fold untold numbers of ways and manners, and with countless many fold untold numbers of mechanisms. All of my children are likewise connected to me, in similar ways and manners, and with similar mechanisms.

As you women, girls, men, and boys sexually rapture, erotem, orgasm, and reach sexual peaks, and then sustain them, you grow holyer, as you become purer, brillianter, and closer in GODLYNESS to ME, GOD.

Obviously, then, the primary means for you to grow pure and holy is to sexalate, and as you continue, over the days, and weeks, then months, years, decades, hundreds of years, thousands of years, millions of years, and more, you slowly grow more pure and holy.

Sexaling is my primary and most fundamental religious practice and your primary religious practice for you to become cleansing machines, washing machines, purifying and sanitizing machines, so that you can clearify and erase your karmic markups, and purify your lives, and the lives of those around you, with your selfless actions of grace and serenity, sexaling and showering purifying energies in all directions for the sake of your self, and for the sake of others.

You women and girls need men and boys to assist you to become the powerful cleansing and purifying machines that you are capable of becoming.

Men and boys used to be somewhat nearly as useful as purifying and cleansing machines, as women and girls, but men and boys have different jobs, and different priorities, and there fore, the burden of work to purify my universe, and to clearify the karmic markups of all my children rests on the shoulders of all women and girls, with men and boys assisting women and girls.

You men and boys need women and girls to lead you, and to help you to become more proficient, powerful, and more capable cleansing, washing, purifying, and sanitizing machines.

Assistive Religious Practices

The practice of praying Nam Myeo Ho Ren Ge Kyeo is an assistive practice that allows you to become in touch with my GOD SELF, equally as well, but the time it takes, is much longer, as very little purifying energies are produced, merely by using your brain, muscles, ligaments, sinews, bones, mouths, tounges, and jaws, as energies sources.

There are many other assistive practices, from meditation, to breathing techniques, to yogic techniques, to ballet like techniques, to dance techniques, to body movements of various kinds, to help you to increase and or also store up your energies, and then for you to release them, for you to then become more firmly and closely connected to ME so that you can eventually begin to gain a higher appreciation of ME, GOD.

My many religions teach many ways to do this, and before my many religions were corrupted by the Lesbianists, they worked to varying degrees of success.

Therefore, sexaling is the primary fundamental religious practice, and all other practices in my religions that I've taught over time, spanning all of my previous teachings from the begining of our time together, since I, my GOD SELF, created you as my children, are assistive practices, of one kind or another.

Sexaling, eroteming, orgasming, phlumetting are important practices, and as you orgasm, you are purifying your self, and others by pushing out and spraying your self with purifying energies as your holy and sacred energies shoot out to cover you and emmerse you in full body coverage, from head to toe, showering and shattering energies every where around you. They then build up and cover over all others who are around you, as well, with your purifying erototistic and orgasotistic purifying energies, clearifying yours and their karmic markups.

Astral traveling is another type of practice, but we'll define it, another time. Experiencing hyper trance states of mind and being, and a nearness to GODLYNESS are also a practice, and we'll define it, when I can remember every thing I need to remember about it.

Participating in my religious ceremonies is an assistive religious practice you can enjoy, as you become purer and holyer, and after you recognize that I am your Mother and Father, and your CREATOR, and that you exist because of me, as I made you from pieces and parts of me, your CREATOR.

After you realize this, you can enjoy participation in ceremonies with me, as training priestesses and priests, and you can make your way up the purity ladder, the more you participate with me, GOD, in my religious prayer hand signaling ceremonies.

Praying Nam Myeo Ho Ren Ge Kyeo to my Holy Body, or to the Gurkian Mandala, as I've explained about, is an assistive practice that will bring results.

It will not bring results as well and as effectively and as quickly, as sexaling, which is the most holy and virtuous practice, along with eroteming, orgasming, phlumetting, astral traveling, peaking, and so on.

I've spoken about peaking, before, and women and girls can peak, and experience wonderful feelings.

In any case, do not confuse assistive practices, with the fundamental and primary practice of sexaling. We'll get back to all those other things, to define them, betterly, another time, after my brain heals, a little bit more, and after I erase more karmic markups that keep my brain karma from improving, fast enough for me.

How To Make Prayer Statements

Remember to include a prayer statement, such as 'I pray to the holy ephemeral body of the Creator, John Francis Ayres, for the [insert private prayer statement]', such as, '... for the serenity of mind, and the gratefulness of heart, for all those around me, who have helped me to become the person I am, and can become.' or, '... for the peace of mind, and serenity of heart, for the love of all men and boys, and the cooperation of all women and girls.' These prayers said by a woman or girl. Men can pray, similarly, '... for the grace and deviness of the women and girls who surround me, I am greatful to them, and I pray for their continued good health, and prosperity'.

You can also say, 'I pray to the holy body of the Creator, John Francis Ayres, for the [insert private prayer statement]', but only when I am in the middle of a religious hand signaling prayer ceremony, i.e., while I am doing a prayer ceremony, and saying my prayers with religious holy hand prayer signals that my special kids who are religious kids, can pick up and then act on, in concert with other groups of kids of mine, who also are religious kids, most of them, I think, and who work together with my primary groups of religious kids.

I have lots of kids, and some are normal kids, who go about their jobs, as expected, for earnings, just as most people we know. But I also have lots of other groups of children, who are more, religiously oriented, to varying degrees, and who are very religious as their work is all for the sake of my religious self, my GOD SELF. My religous kids catch my hand signing, and then they pass the messages along to others of my groups of children, and with all of the different groups of children I have doing 'good' works for me, as well as groups of children who do 'religious' works for me, as well as groups of children doing normal work for me, but for the sake of my religion, nevertheless.

They all coordinate themselves, somehow, I have yet to figure out how they do it, but between them all, they get the jobs done, that I ask them to do, while I am religiously - and the prayer statements I am signing are very holy - hand prayer signaling, i.e., hand signing.

So, unless you know for a fact, by seeing me on a tv, such as during a live broadcast, once I get my religious conveyance set up, and built by my children, after all the conditions are met, for securing this world from the grasps of the Lesbianists, and after killing all the Lesbianists, and / or after making the remaining Lesbianists surrender, and then after all other conditions are met, as I don't know all the conditions, I've set, as my memories are still foggy, as I'm amnesiatic, as well as mentally retarded, but in any case, if you see me on tv, on a live broadcast, doing my hand signing, you'll know I'm in the middle of one of my prayers, and then you can say, 'I pray to the holy body of the Creator, John Francis Ayres, for the [insert private prayer statement]', and you can omit the 'ephemeral' if you like, as it will work better if you omit the word 'ephemeral' as while I'm praying, I'm my normal, GOD, self, though I may not look to you, on the surface, to be any different, over the video links, or even in person. It never the less works better if you use my recommended methods of making prayer statements, this way, for you to maximize your private prayer statements.

All of my groups of kids have lots of friends, and they do lots of work for me, and I do not remember how many groups of them there are, and how many children I"ve got, as yet, but in time, I'll be able to give you a better idea of how they work together to get the work done, that I ask them to do for me, with my religious hand prayer signals, or hand signals, as in hand signing, or signing.

My kids use signing for all their work assignments, so I use hand signing that they can catch, pick up and read, and it is all pretty much very religious in nature, and it is very solemn, as I am GOD, and when I'm signing, they know I'm GOD, and do not doubt it.

When I am not signing, they might now and then, doubt that I am GOD, but never the less, I am GOD, and my signing proves it to them - when I am saying my religous hand prayer statements, by hand signing - with out any room for doubts in their minds.

In other words, I'm a typical person, just a little mentally retarded, brain smattered, or brain damaged, after my many youthful and other brain bashings I recieved, the wiring is a little scrambled up, upstairs, and after many poisonings by the Lesbianists - from makeing coffee from kerosene, diesel fuel, gasoline, and motor oil contaminated coffee beans and then from drinking that coffee, without knowing it was contaminated with petrol fluids, as often happens to people - and with ill health karma that has me on disability, and I've been through a lot, life after life, and sometimes, my children may have had a thought or two, 'I wonder, if he is going to make it, like he said he would?'

Well, to dispel all doubts, I sign, and when I'm signing, I remind them of my old self, back in the old days, when I used to sign, religiously, and they know how serious a guy I was, so they do not harbor any doubts, so long as I am hand signing.

What To Say, When You See Me Using My Dick Or Other Parts Of My Body To Purify Others, And So Forth

You can say, 'I pray to the holy body of the Creator, John Francis Ayres, for the [insert private prayer statement]', also while you see me praying, Nam Myeo Ho Ren Ge Kyeo, or also while you see me in a ceremony, using my dick and scrotum, or other parts of my Holy Body to purify others, during the middle of a prayer ceremony, and I need not be hand signing, or praying Nam Myeo Ho Ren Ge Kyeo, as I am in the middle of prayers and activities ceremony, which is just as good as a religious hand prayer signaling ceresony, any day.

My dick and scrotum package is very Holy, and it has a very useful function, and that is, it purifying others. My lips do, too, and my butt hole, does as well. They all purify others very effectively and efficiently during my religious ceremonies.

My entire body, during a religious ceremony, butt hole, mouthal hole, lips, tounge, cheeks, legs, knees, feet, toes, butt, chest, back, arms, elbows, hands, fingers, head, neck, throat, ears, nose, and so forth, is entirely the body of GOD, as I am GOD, and therefore, while I am useing my body, during my religious ceremonies, and for my religious ceremonies, and you see me on tv doing so, then after you have verified that I am in the middle of a prayer ceremony, you can say your private prayer, in the manner as I've explained, 'I pray to the holy body of the Creator, John Francis Ayres, for the [insert private prayer statement]'.

I only use my dick and scrotum package for prayer ceremonies, except when I need to pee, so if you see that I am using it, during a prayer ceremony, or if you see me using any other part of my Holy Body, during a live broadcast prayer ceremony, then you'll know right away, that I am in the middle of a prayer ceremony and it is okay to use the statement, 'I pray to the holy body of the Creator, John Francis Ayres, for the [insert private prayer statement]'.

The same is true, pretty much, for any priestess or priest, who practices with me, in my religious holy body prayer circle, their bodies become very Pure, Holy, and Devine, but only after many life periods, that is, after many, many aeons, as they do not attain the same level of purity for a while, the same level of purity as I am at by my good old self, or the same level of pureness that is of ME, GOD, since I'm GOD, and they are not.

That means, it takes priestesses and priests longer to become pure, holy, and devine. I happen to be pure, holy, and devine, but that's because I'm GOD, and it is only during my religious ceremonies that you can understand that as you make your prayer statements, and sexal, etc.

After a long, long while, priestesses and priests will also become pure, holy, and devine, as their holy bodies, energies bodies that are pure, holy, and devine, but on a lower scale than are MY energies

bodies, since I'm GOD, and I'm in charge of keeping things tied together, here in my universe.

After many aeons plus years of practice in my holy body praryer circle, the priestesses and priests become pure, holy, and devine, and then their bodies, their normal bodies, become very purifying, just as mine is, now, when I am in a prayer ceremony. I am in a prayer ceremony, daily, a few times, to a number of times, a day.

I've gone eighteen hours straight, once, and no sooner than I go to sleep, and then wakup, right away, I begin again, and I've gone many days, straight, praying, continuously, non-stop.

This is nothing, though, and is all preparatory, as in the future, when I get my health back, as I haven't been too healthy, for quite some time, I will be praying around the clock, some days, and for many days at a time, taking a break only to eat, drink, poop, pee, and clean up.

When priestesses and priests join with me, we will go for years without stopping, and with the priestesses, and with the priests, the both of them there, present, doing the prayer ceremony on my behalf, they can represent me, while I take a nap, go and shower, get some food, nourish myself, drink some fluids, read a book or news paper, or watch the news, or a movie, game show, video, or play a video game, and so forth. I won't be taking long breaks, and that is very funny sounding, but anyway, it happens that priestesses and priests will lose their attention, and then get lost, somehow, and then go and watch tv in their bed room, or whatever, and then we have to go and look for them, and they will get a few markoffs, and with enough markoffs, they will be asked to leave the religious conveyance, and they will be put on a type of vrobatiton, or under survielance, to see if they are good or not. My kids do all my survielance work, and they keep track of every one, so 'you'd better be good, you'd better be nice, you'd better look smart I'm telling you why, Santa Clause is coming, to town'.

Who Was Kris Kringle?

Did you know that Kris Kringle got its start from me? What a coincidence. I don't think he was wearing anything, though, or rather, I don't think I was wearing any thing, but you never know, as tolerances have changed over the long aeons of time, as they pass.

When priests and priestesses become that pure, holy, and devine, as pure, holy, and devine as I am, after their many aeons of religious practice in my holy body prayer circle - pure and devine on the exact same level as I am at - then they can represent me, as Mr. mini-GOD, and Mrs. mini-GOD.

You can not represent me as Kris Kringle, and whoever my wife was, back then. I think I had a lot of guys on that team, and a lot of women and girls, too, since sexaling was a part of that religion, too.

You can learn more about it, if you're interested, by getting a day pass, and checking in with my kids, and then, signing up and joining our country, and then by becomeing a citizen, as I've spoken about, before.

You can include any good prayer, that comes to mind, that you feel is needed by you, to improve your life, and to level up your life.

You are the only ones who can pray, and practice, you women, girls, men, and boys, and there fore you are connected to me in many more ways than other living beings, the animals, and the amoebes, cells, and other living beings.

There fore, you are, both genders, the ones who will clean up the mess you have made, and you will continue to keep my universe clean, as you sexal with your genitals, and with your bodies, and with all your gizmos, igniters, trigger mechanisms, love bumps, love patches, tuning forks or ticklements, and so forth, as you are sexaling beings, who I, GOD, created, and you will sexalate, erotem, orgasm, phlumett, astral travel, peak, hyper tranceate, and so forth, just as I intended you to, from now till forever.

You will become virtuous and worthyable beings, worthyable tummy mommies, and worthyable tummy daddies, with your practice of my religion, who will bring into my universe, my many children who will join with you, and assist you and me, in cleaning up our universe, and the mess you have all made of it.

Is that understood? The answer had better be, "YES SIR!".

Lesbianists' Torment Campaign Under Way

Lesbianists are clearly releaseing wierd, ghastly, horrible, and dangerous preditorial animals, giant insects, giant spiders, giant lizards, snakes, and reptiles, ghastly, preditorial sea animals and sea mammals, winged, preditorial and horrific, aggressive scavenger and killer buzzard like creatures and other winged and destructive animals, and other horrible creatures, as well as my abominant kids to kill, maime, torture, and cause major disruptions and suffering to people, around the globe, in many locations.

Apparently, the whole world is now affected, or will be affected, by this dischordance and disharmonic display of defeated lunacy.

The peace has been shattered by the Lesbianists. It was not good before, the situation in the world, with the balooneying governments of the world, doing what they wanted to do, and torturing, and canabalizing people, and feeding people to my abominant cave bears kids, and to my crocodile people kids, and mistreating people, like Bill Gates, Steve Hawkins, Steve Irwin, many women, young girls, and men.

The war in Iraq, the phoney Saddam Hussein Trials, and all the bogus manipulation of the press and media, and the suppression of what is actually the case, with our being used and abused, poisoned, and maltreated by the Lesbianists, was a rotten situation. That was normal, or normality for us. Our karma is very poor, and we have the karma to suffer this abuse, and these torments, daily, unknowingly, in most if not nearly all cases.

But, it is becomeing really bad and there is need for serious concern, and action, to correct this situation. It has gotten out of hand, completely, and there is no stopping the Lesbianists in their wanton, and coldly miserable wish and lust for chaos and disturbances to others.

Now, more clearly than ever, as the Lesbianists rampage, the Lesbianists are causing major disruptions, suffering, anguish, and there is just an awful discordance of shock, dismay, and misery, that is growing, every moment. This is as real as the sunlight shining from the sun on a hot day in summer.
